

# Advanced combinatorial testing of software and systems using covering arrays

- Advanced
  - High strength  $t$ -way testing
  - Support complex constraints
- Made possible by use of covering arrays

  - Technology Innovation Program

# Outline

- Discuss development of Combinatorial Testing (CT) as adaptation of Design of Experiments (DoE) methods
- Special aspects of CT for software and systems
- Limitations of Orthogonal Arrays (OAs), benefits of Covering Arrays (CAs) for generating combinatorial test suites for testing software and systems

# Combinatorial testing is a variation of Design of Experiments (DoE) adapted for testing software

- Example of DoE: Five test factors
  - Viscosity {a} with 2 values {0, 1}
  - Feed rate {b} with 2 values {0, 1}
  - Spin Speed {c} with 2 values {0, 1}
  - Pressure {d} with 2 values {0, 1}
  - Materials {e} with 4 types {0, 1, 2, 3}
- Combinatorial test structure  $2^4 \times 4^1$ 
  - Number of possible test cases:  $2^4 \times 4^1 = 64$
- Object: evaluate only “main effects” of five factors
- Possible to evaluate main effects from 8 test cases only determined using orthogonal array  $OA(8, 2^4 \times 4^1, 2)$

# DoE based on orthogonal array: OA(8, 2<sup>4</sup>×4<sup>1</sup>, 2)

Strength 2: every two columns contain all pairs exactly once or exactly twice

	<u>a</u>	<u>b</u>	<u>c</u>	<u>d</u>	<u>e</u>	data
1.	0	0	0	0	0	y <sub>1</sub>
2.	1	1	1	1	0	y <sub>2</sub>
3.	0	0	1	1	1	y <sub>3</sub>
4.	1	1	0	0	1	y <sub>4</sub>
5.	0	1	0	1	2	y <sub>5</sub>
6.	1	0	1	0	2	y <sub>6</sub>
7.	0	1	1	0	3	y <sub>7</sub>
8.	1	0	0	1	3	y <sub>8</sub>

- Associate factors with columns, test values {0, 1}, {0, 1, 2, 3} with entries
- Rows of OA specify 8 test cases
- Every test value paired with each value of every other factor
- Main effect of factor a:  
 $(y_2+y_4+y_6+y_8)/4 - (y_1+y_3+y_5+y_7)/4$
- All test values of every other factor represented in each average of four

# DoE balanced, software test suite need not be

- DoE plans can be expressed in matrix form
  - Columns: test factors, Entries: test values, Rows: tests cases
- In DoE “main effects” and “interaction effects” linear contrasts of response data
  - Binary factors: difference of two averages of half data
  - Main effect of factor  $\underline{a}$ :  $(y_2+y_4+y_6+y_8)/4 - (y_1+y_3+y_5+y_7)/4$
  - For main effects to be meaningful, DoE must be balanced
- In testing software and systems “interaction” means “joint combinatorial effect of two or more factors”
- CT suite for testing software need not be balanced because DoE type “main effects” not relevant, statistical models not used in data analysis

# Example: Font effects on word processing

# Factors values and test cases

- Each factors (font effects) can be turned on or off
  - Ten binary test factors with test values {0, 1}
- Combinatorial test structure  $2^{10}$
- Possible test cases  $2^{10} = 1024$  too many to test
- Suppose no failure involves more than 3 factors jointly
  - Sufficient to test all triplets of factor values
- Number of triplets =  $\binom{10}{3} 2^3 = 960$
- How many test cases needed to test all 960 triples?
- How to determine those test cases?

All 960 triples can be covered by 13 test cases determined using covering array CA(13,  $2^{10}$ , 3)

Rows	Factors									
	1	2	3	4	5	6	7	8	9	10
1	0	0	0	0	0	0	0	0	0	0
2	1	1	1	1	1	1	1	1	1	1
3	1	1	1	0	1	0	0	0	0	1
4	1	0	1	1	0	1	0	1	0	0
5	1	0	0	0	1	1	1	0	0	0
6	0	1	1	0	0	1	0	0	1	0
7	0	0	1	0	1	0	1	1	1	0
8	1	1	0	1	0	0	1	0	1	0
9	0	0	0	1	1	1	0	0	1	1
10	0	0	1	1	0	0	1	0	0	1
11	0	1	0	1	1	0	0	1	0	0
12	1	0	0	0	0	0	0	1	1	1
13	0	1	0	0	0	1	1	1	0	1

# Early history of combinatorial testing for software and systems

- Mandl (1985) “Use of orthogonal Latin squares for testing Ada compiler” often cited first publication
  - Special case of orthogonal arrays
- Japan/mid-1980s OAs used for testing hardware-software systems: Tatsumi (1987), Tatsumi et al (1987)
- USA/late-1980s descendent orgs of AT&T (Bell Labs, Bellcore-Telcordia) exploring use of OAs for combinatorial testing; developing tools based on OAs: Brownlie et al (1992), Burroughs et al (1994)
- In 1990s use of OAs for testing of computer and communication hardware-software systems expanded

# Tools for generating combinatorial test suites

- Early tools for generating test suites for pairwise testing
  - OATS (Phadke AT&T) 1990s (not public)
  - CATS (Sherwood AT&T) 1990s (not public)
  - AETG (Cohen et al Telcordia) 1997 (commercial)
  - IPO (Yu Lei NCSU) 1998 (not public)
- Czerwonka (Microsoft) lists 34 tools ([www.pairwise.org](http://www.pairwise.org))
  - Tconfig
  - CTS
  - Jenny
  - TestCover
  - DDA
  - AllPairs
  - AllPairs[McDowell]
  - PICT
  - EXACT
  - IPO-s
- ACTS (NIST/UTA): freely distributed
  - Primary algorithm: IPOG generalization of 1998 IPO (Yu Lei UTA)

# NIST investigated actual faults to determine what kind of testing would have detected them

Medical devices recall data, Browser, Server, NASA distributed database, Network security system

# Pairwise testing may not be adequate

- Kuhn et al (2001, 2002, 2004)
  - 2-way testing could detect 65 % to 97 % faults
  - 3-way testing could detect 89 % to 99 % faults
  - 4-way testing could detect 96 % to 100 % faults
  - 5-way testing could detect 96 % to 100 % faults
  - 6-way testing could detect 100 % faults in all cases investigated
- Kera Bell (2006, NCSU) arrived similar conclusion
- Empirical conclusion: pairwise (2-way) testing useful but may not be adequate; 6-way testing may be adequate

# Combinatorial high strength ( $t$ -way) testing

- Dynamic verification of input-output system
  - against its known expected behavior
  - on test suite of test cases selected such that
  - all  $t$ -way combinations are exercised with the
  - object of discovering faults in system
- Earlier combinatorial test suites based on orthogonal arrays of strength 2 useful for pairwise (2-way) testing
- Now tools available for high strength  $t$ -way testing
  - ACTS (NIST/UTA) 2009
  - Primary algorithm is IPOG, generalization of IPO for  $t > 2$
  - ACTS has built-in support of constraints
  - <http://csrc.nist.gov/groups/SNS/acts/index.html>
  - Freely downloaded by over 800 organizations and individuals

# Special aspects of CT for software and systems-1

- System Under Test (SUT) must be exercised (dynamic verification)
- CT does not require access to source code
- Expected behavior (oracle) for each test case be known
  - determined from functionality and/or other information
- In CT actual behavior is compared against expected for each test case with final result of pass or fail
- Objective of CT to reveal faults; a failure indicates fault, a fault always results in failure
- Repeat of a  $t$ -way combination gives same result so no need to repeat  $t$ -way combinations in test suite

# Special aspects of CT for software and systems-2

- Numbers of test values of factors may be different
- A test case is combination of one value for each factor
- Certain test cases invalid, incorporate constraints
- From pass/fail data identify  $t$ -way combinations which trigger failure among actual test cases (fault localization)
- No statistical model used in data analysis: test plan need not be balanced like classical DoE
- Choice of factors and test values highly critical for effectiveness of combinatorial testing
  - Information about nature of faults to be detected helpful

# Orthogonal arrays

- Fixed-value  $OA(N, v^k, t)$  has four parameters  $N, k, v, t$ : It is a matrix such that every  $t$ -columns contain all  $t$ -tuples the same number of times
  - For OAs strength  $t$  is generally 2
  - Index of OA is number of times every  $t$ -tuple appears
  - Another notation  $OA(N, k, v, t)$
- Mixed-value orthogonal array  $OA(N, v_1^{k_1} v_2^{k_2} \dots v_n^{k_n}, t)$  is a variation of fixed value OA where  $k_1$  columns have  $v_1$  distinct values,  $k_2$  columns have  $v_2$  values, ...,  $k_n$  columns have  $v_n$  values  $k = k_1 + k_2 + \dots + k_n$

# Covering arrays

- Fixed-value  $CA(N, v^k, t)$  has four parameters  $N, k, v, t$ : It is a matrix such that every  $t$ -columns contain all  $t$ -tuples at least once
  - For CAs strength  $t$  can be any integer  $k$  or less
  - $OA(N, v^k, t)$  of index one is covering array with min test cases
  - However OA of index 1 are rare
  - Most CA are unbalanced
  - Another notation  $CA(N, k, v, t)$
- Mixed-value covering array  $CA(N, v_1^{k_1} v_2^{k_2} \dots v_n^{k_n}, t)$  is a variation of fixed value CA where  $k_1$  columns have  $v_1$  distinct values,  $k_2$  columns have  $v_2$  values, ...,  $k_n$  columns have  $v_n$  values and  $k = k_1 + k_2 + \dots + k_n$

Combinatorial structure  $2^4 \times 3^1$ , need strength  $t = 2$   
OA for  $2^4 \times 3^1$  dose not exist

OA(8,  $2^4 4^1$ , 2)

	<u>a</u>	<u>b</u>	<u>c</u>	<u>d</u>	<u>e</u>
1.	0	0	0	0	0
2.	1	1	1	1	0
3.	0	0	1	1	1
4.	1	1	0	0	1
5.	0	1	0	1	2
6.	1	0	1	0	2
7.	0	1	1	0	3 2
8.	1	0	0	1	3 2

CA(8,  $2^4 3^1$ , 2)

	<u>a</u>	<u>b</u>	<u>c</u>	<u>d</u>	<u>e</u>
1.	0	0	0	0	0
2.	1	1	1	1	0
3.	0	0	1	1	1
4.	1	1	0	0	1
5.	0	1	0	1	2
6.	1	0	1	0	2

# OAs useful but have limitations

- OAs do not exist for many combinatorial test structures
  - Construction requires advanced mathematics
  - <http://www2.research.att.com/~njas/oadir/>
- Most OAs of strength  $t = 2$ ; some  $t = 3$  recent
- Most fixed-value; some mixed value OAs recent
- Combinatorial test structure fitted to suitable OA
  - We saw how  $OA(8, 2^4 \times 4^1, 2)$  can be used for  $2^4 \times 3^1$
- Constraints destroy balance property of OA

# Benefits of CAs for generating test suites

- CAs available for any combinatorial test structure
- CAs available for any required strength ( $t$ -way) testing
- For a combinatorial test structure if OA exists then CA of same or fewer test runs can be obtained
- When numbers of factors large, CAs of few tests exist
- Generally CAs not balanced (like OAs) not needed in software testing
- Certain tests invalid, constraints can be incorporated
  - Coverage defined relative to valid test cases

# Test suite for 2-way testing based on covering array

An application must run on various 3-OS, 2-Browser, 2-Protocol, 2-CPU type, and 3-DBMS, combinatorial test structure:  $2^33^2$

Test	OS	Browser	Protocol	CPU	DBMS
1	XP	IE	IPv4	Intel	MySQL
2	XP	Firefox	IPv6	AMD	Sybase
3	XP	IE	IPv6	Intel	Oracle
4	OS X	Firefox	IPv4	AMD	MySQL
5	OS X	IE	IPv4	Intel	Sybase
6	OS X	Firefox	IPv4	Intel	Oracle
7	RHL	IE	IPv6	AMD	MySQL
8	RHL	Firefox	IPv4	Intel	Sybase
9	RHL	Firefox	IPv4	AMD	Oracle
10	OS X	Firefox	IPv6	AMD	Oracle

All pairs of values of five factors covered by 10 test cases

# Size of test suites for various values of $t$ based on CA

Combinatorial test structure:  $2^3 3^2$

$t$	# Test cases	% of Exhaustive
2	10	14
3	18	25
4	36	50
5	72	100

# Android smart phone configuration options

## Combinatorial test structure: $3^3 4^4 5^2$

# Size of test suites for various values of $t$ based on CA

Combinatorial test structure:  $3^3 4^4 5^2$

$t$	# Test Cases	% of Exhaustive
2	29	0.02
3	137	0.08
4	625	0.4
5	2532	1.5
6	9168	5.3

# Some comments on Combinatorial *t*-way testing

- CT one of many complementary testing methods
- CT can reveal faults, not guarantee their absence (in this sense software testing is about risk management)
- CT can reveal many types of faults
- CT can be used in unit, integration, system testing
- CT better than random (fewer test runs); may be better than human generated test suites (better coverage)

# ACTS tool

# Combinatorial testing is a generic methodology

- Software testing
  - Test input space, test configuration space
- Computer/network security
  - Network deadlock detection, buffer overflow
  - <http://csrc.nist.gov/groups/SNS/acts/index.html>
- Testing Access Control Policy Systems
  - Security, privacy (e.g. health records)
  - <http://csrc.nist.gov/groups/SNS/acpt/index.html>
- Explore search space for study of gene regulations
  - <http://www.plantphysiol.org/content/127/4/1590.full>
- Optimization of simulation models of manufacturing
  - <http://publications.lib.chalmers.se/cpl/record/index.xsql?pubid=103117>

# Summary

- Combinatorial testing is a variation of DoE adapted for testing software and hardware-software systems
- Early use was limited to pairwise (2-way) testing
- Investigations of actual faults suggests that up to 6-way testing may be needed
- Combinatorial  $t$ -way testing for  $t$  up to 6 is possible by use of covering arrays
- ACTS is useful tool for generating  $t$ -way test suites based on CAs, supports constraints
- Combinatorial testing useful when testing expressed in terms of factors, discrete test values, critical event happens when certain  $t$ -way combination encounters
