- Low evaluation cost
- Large security margin
- Implementation

# Lessons from SHA-1

- Difficult to analyze
  - difficult to find the best differential trail
  - it took **10 years** to break it
- Not that secure
  - Large differential probability
    - SHA-1:  $2^{-83}$  for steps 17--80 (2005)

# Lessons from SHA-1

How to design a hash function with **low evaluation cost against differential attack?**

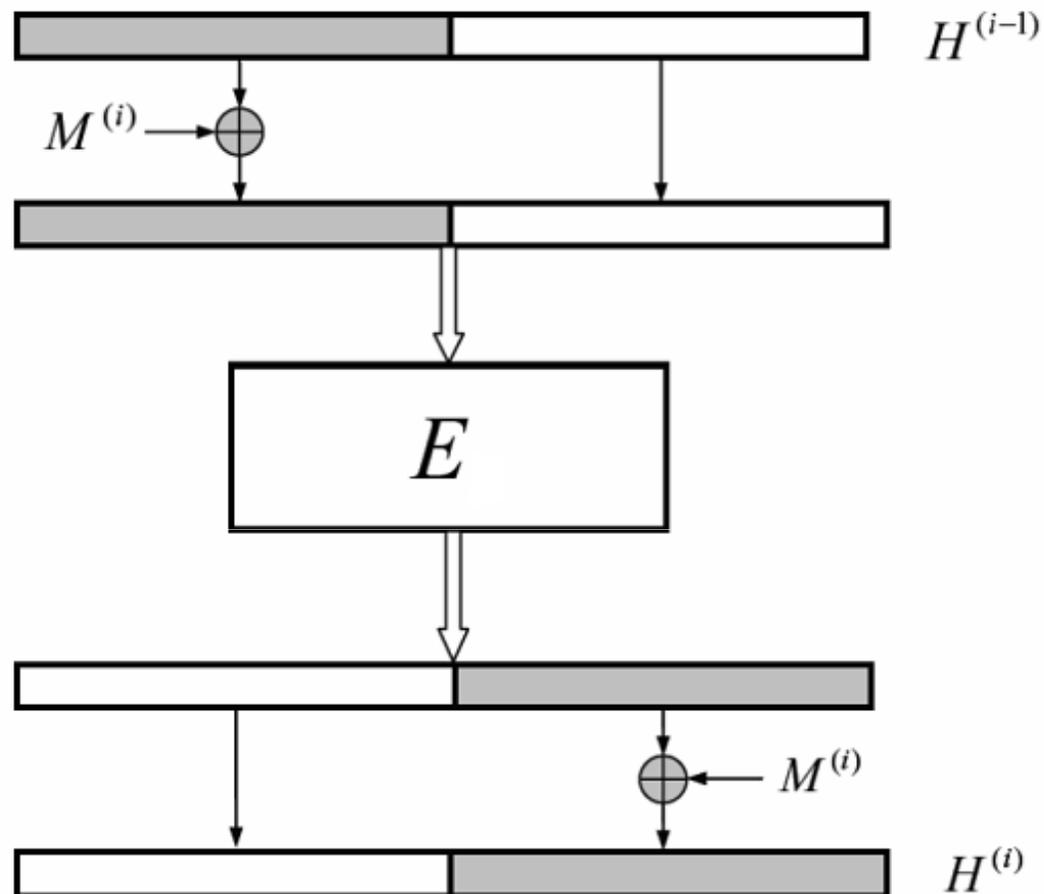

=> JH was designed to solve this problem

# Low Evaluation Cost

- Low evaluation cost of JH against differential attack due to:
  - JH compression function structure
    - Analyze the differential propagation in only **one permutation**
  - SPN+MDS in JH
    - Easy to find the best differential trail

# Low Evaluation Cost

- JH compression function structure

# Low Evaluation Cost

- JH compression function structure
  - New
  - Resist the rebound collision attack
  - Need to analyze the differential trail in only one permutation
- DM, MMO
  - Need to analyze the interaction between two differential paths

# Low Evaluation Cost

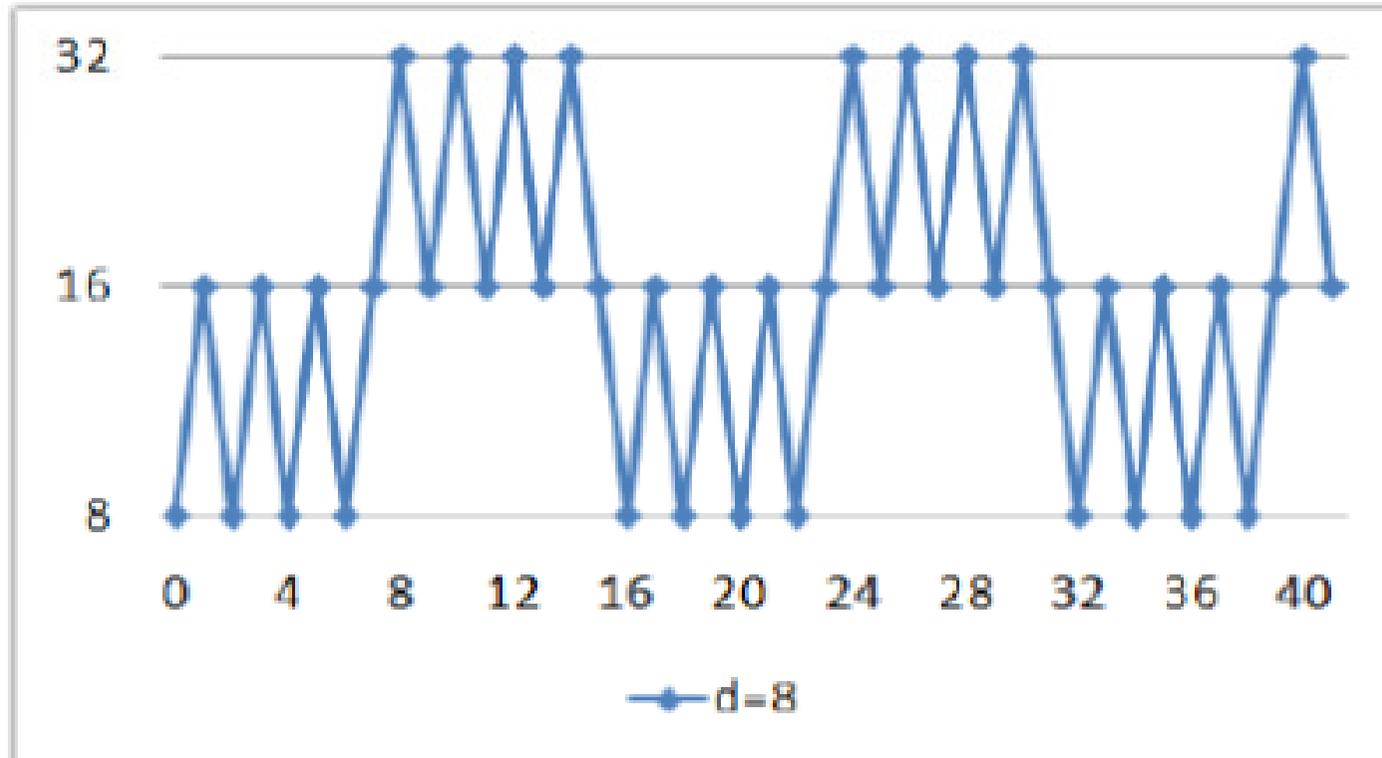

- SPN+MDS (8-dimensional array in JH)
  - SPN + MDS (Rijndael approach) can be analyzed easily against differential attack
    - Easy to find the best differential trail in short period
  - ARX is probably the most difficult to analyze against differential attack

# Low Evaluation Cost

- The evaluation cost of JH against the differential/truncated differential attack is low
  - I was able to finish the analysis before submission
  - My student independently verified the differential/truncated differential attack within 4 months (learning + analysis + coding)
    - TAN Yong Seng. Cryptanalysis of JH, Final Year Project Report, NTU, 2010/2011

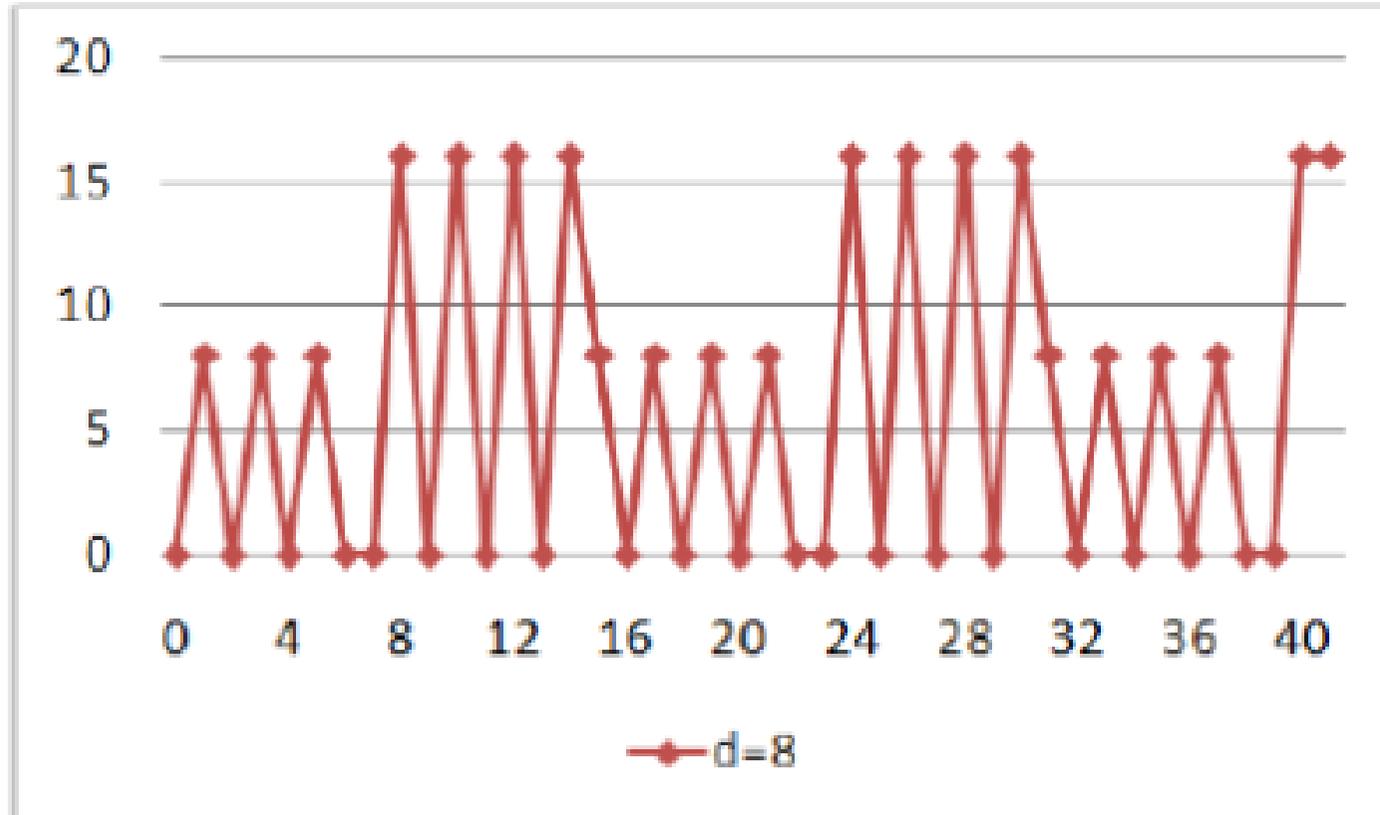

# Low Evaluation Cost

Number of active sboxes in differential attack (Tan, 2011)

# Low Evaluation Cost

Number of shrinkings in truncated differential attack (Tan, 2011)

# Large Security Margin

- Truncated differential attack is the most powerful attack against JH
- JH has large security margin against truncated differential attack that can be easily verified:
  - Assume that message modification can remove 16 rounds, the complexity of the truncated collision attack is **more than  $2^{512}$**
  - Assume that message modification can remove 24 rounds, the complexity of the truncated collision attack is **more than  $2^{400}$**

# Large Security Margin

- Recent rebound attack on JH
  - Naya-Plasencia, Toz, Varici, Asiacrypt 2011
  - Semi-free-start near-collision attack on 37 rounds
  - Complexity:  $2^{352}$
- Does this attack affects the differential collision security margin of JH?
  - No.
  - The JH structure is strong against the rebound attack , and the message size is half of the state size

# Large Security Margin

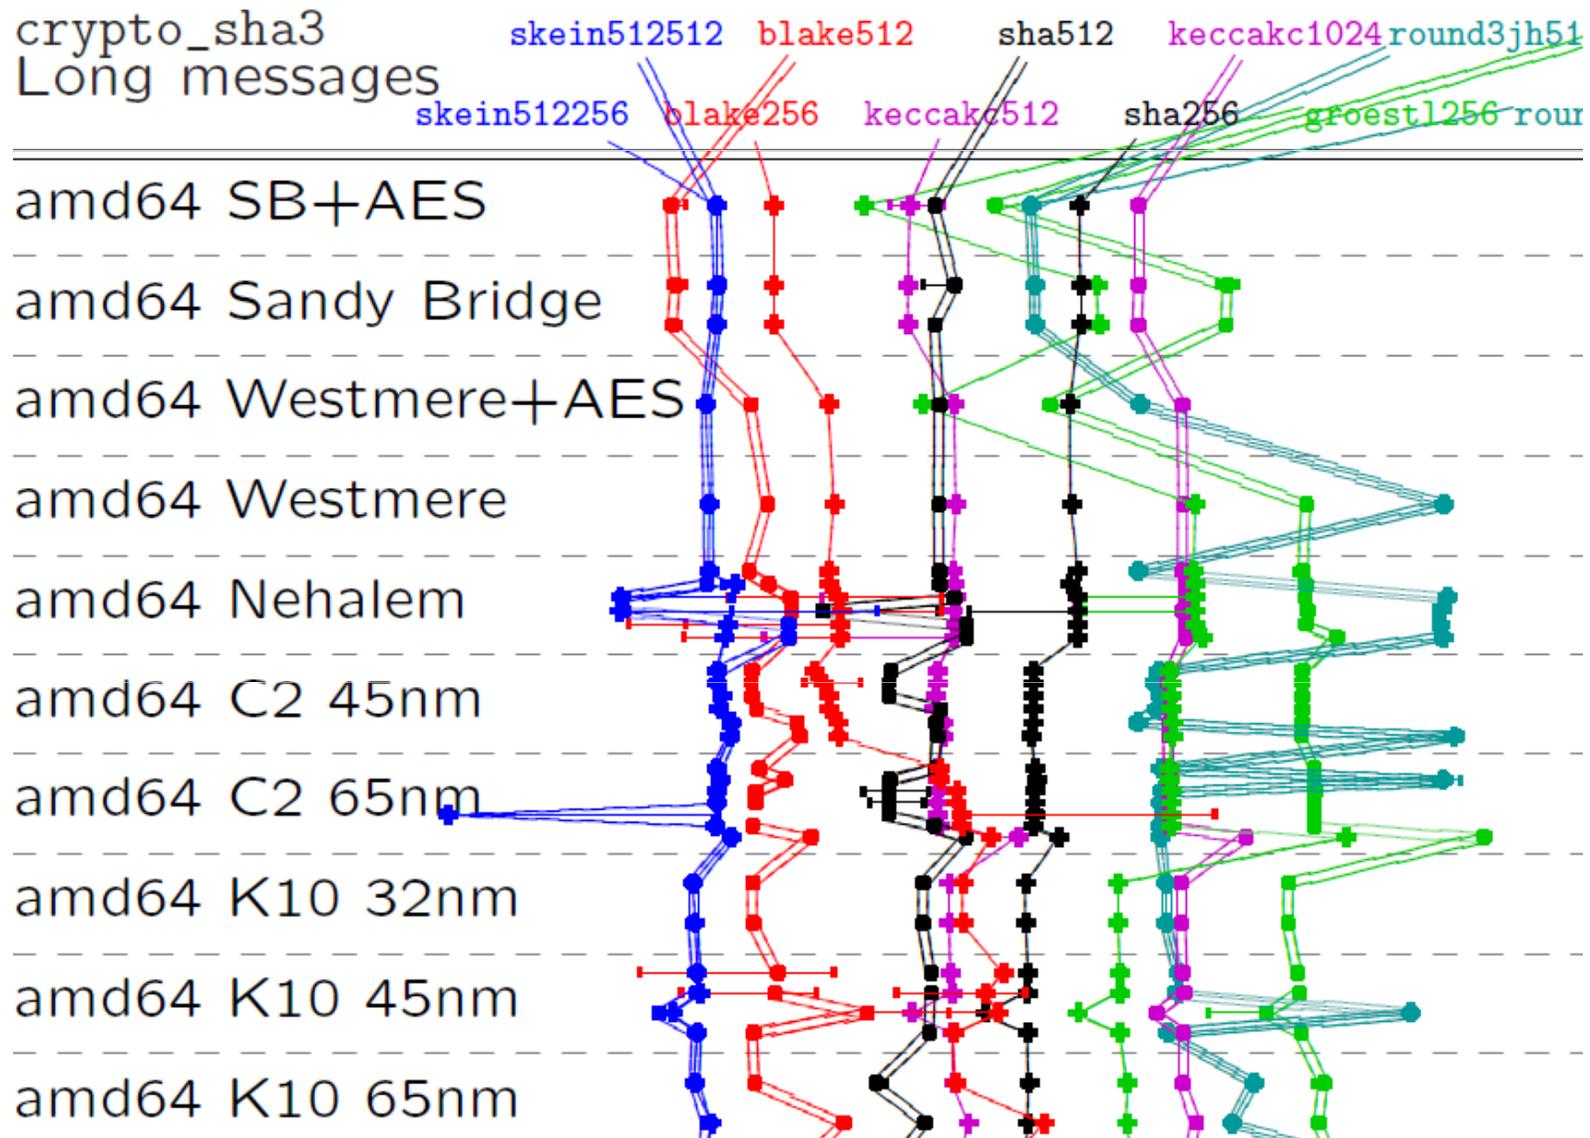

- Security proof of compression function structure:
  - Indifferentiable with less than  $2^{256}$  queries  
(Andreeva et al., Paul et. al., the 3<sup>rd</sup> SHA-3 conference)

# Software Implementation

- Fully benefit from the 128-bit SIMD instructions available on many platforms:
  - Common Intel/AMD CPUs
  - Neon SIMD in ARM CPUs
- The Sbox computation benefits from 256-bit AVX instruction

# Software Implementation

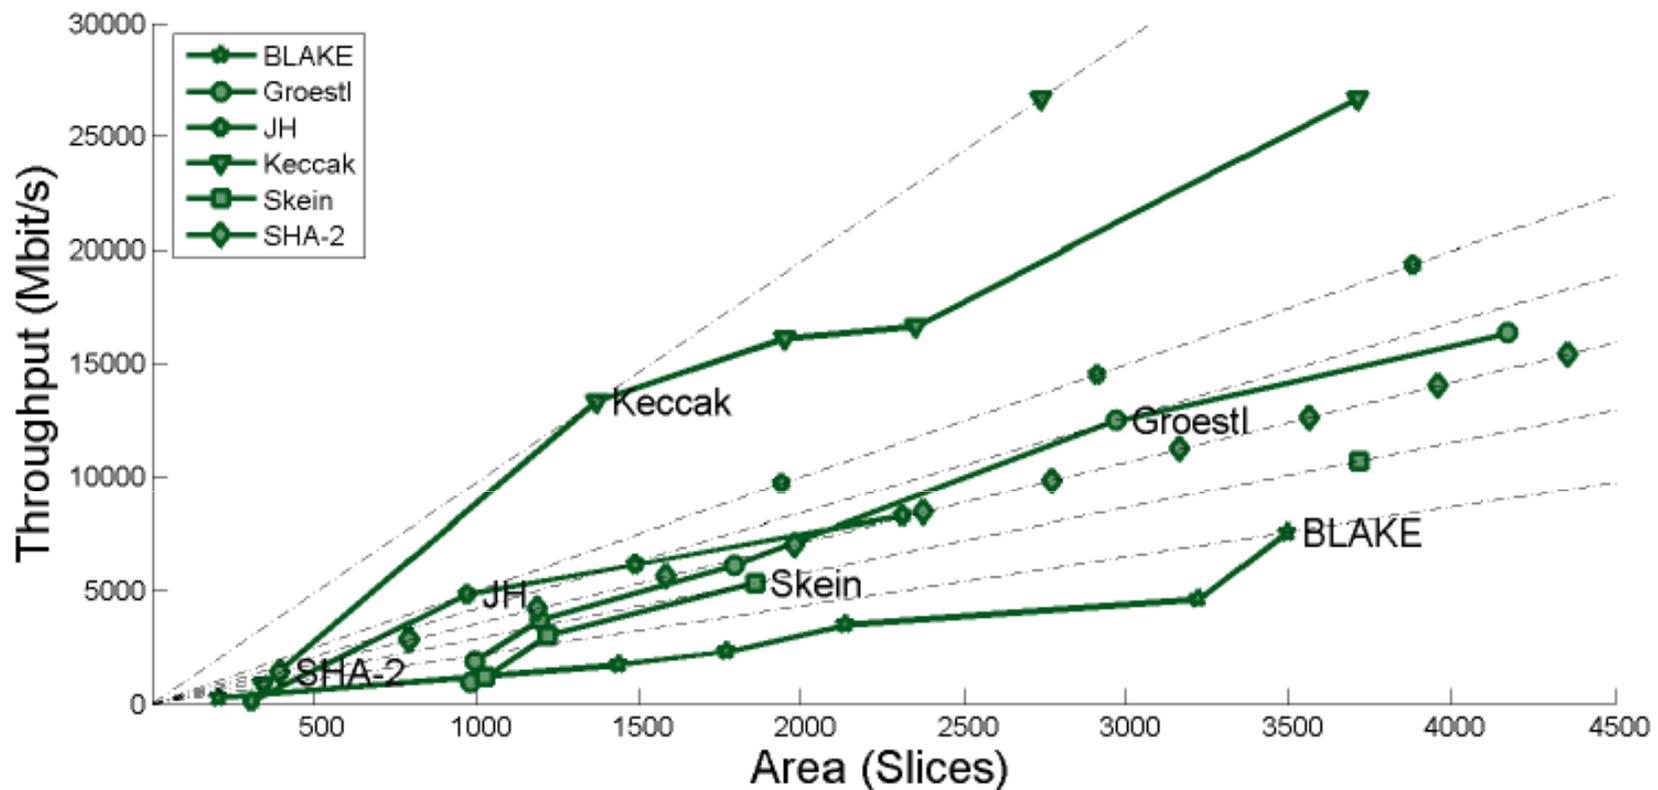

(Bernstein, Lange, the 3<sup>rd</sup> SHA-3 conference)

# Efficient Implementation: Hardware

(Gaj, The 3<sup>rd</sup> SHA-3 Conference)

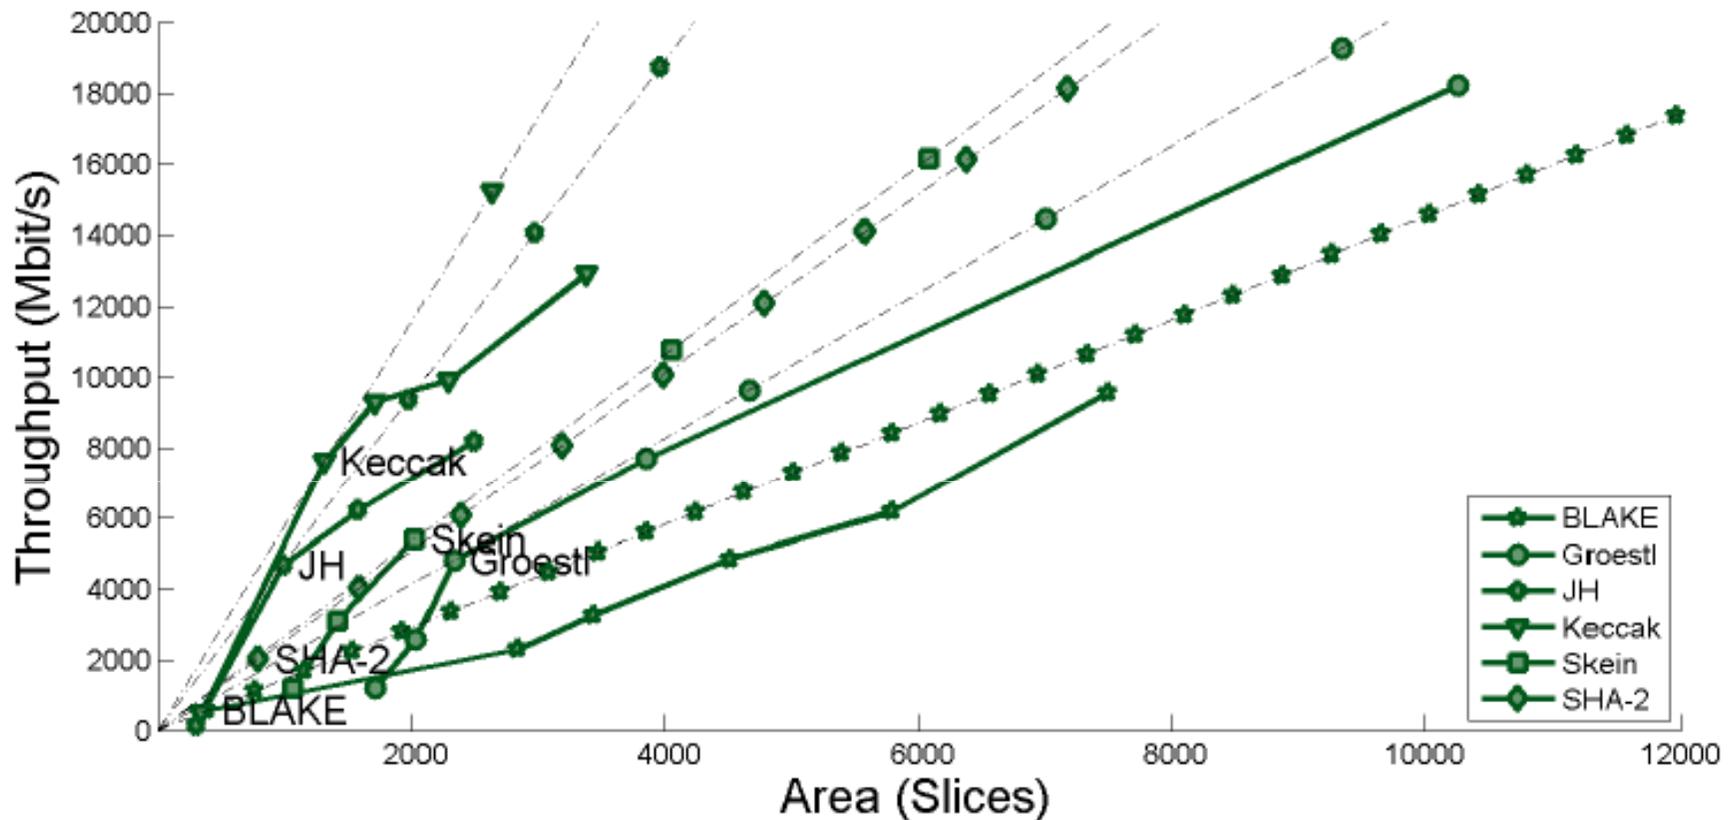

## 256-bit variants in Virtex 5

# Efficient Implementation: Hardware

(Gaj, The 3<sup>rd</sup> SHA-3 Conference)

## 512-bit variants in Virtex 5

# Efficient Implementation

- Flexible design

- If we need a light-weight hash function

- Just use the 6-dimensional array in JH

- **4 times smaller than JH**

- Achieve about **128-bit security** for collision, preimage and second-preimage, no resistance against length-extension

(if we need a light-weight hash function, we do not need 256-bit preimage resistance)

# Conclusion

- JH can be analyzed easily against differential/truncated differential attack
- JH has large security margin against differential/truncated differential attacks
- JH fully benefits from SIMD instruction
- JH is very fast in hardware

# Acknowledgements

- Thanks to NIST
  - It is not that difficult to design a hash function today,
  - but it is difficult to select from 64 submissions
- Thanks to all the researchers
  - for implementing and analyzing JH
- Thanks to Prof Preneel
  - for the suggestion on round number

# Q & A
