
Microsoft Windows Server 2008 Operating System

FIPS 140-2 Security Policy Document

This document specifies the security policy for the Microsoft Windows Cryptographic Primitives Library (BCRYPT.DLL) as described in FIPS PUB 140-2.

August 28, 2012

Document Version: 1.5

1 Cryptographic Module Specification
The Microsoft Windows Cryptographic Primitives Library is a general purpose, software-based, cryptographic module. The primitive provider functionality is offered through one cryptographic module, BCRYPT.DLL (version 6.0.6001.22202, 6.0.6002.18005, and 6.0.6002.22872), subject to FIPS-140-2 validation. BCRYPT.DLL provides cryptographic services, through its documented interfaces, to Windows Server 2008 components and applications running on Windows Server 2008.

The cryptographic module, BCRYPT.DLL, encapsulates several different cryptographic algorithms in an easy-to-use cryptographic module accessible via the Microsoft CNG (Cryptography, Next Generation) API. It can be dynamically linked into applications by software developers to permit the use of general-purpose FIPS 140-2 Level 1 compliant cryptography.

1.1 Cryptographic Boundary
The Windows Server 2008 BCRYPT.DLL consists of a dynamically-linked library (DLL). The cryptographic boundary for BCRYPT.DLL is defined as the enclosure of the computer system, on which BCRYPT.DLL is to be executed. The physical configuration of BCRYPT.DLL, as defined in FIPS-140-2, is multi-chip standalone.

2 Security Policy
BCRYPT.DLL operates under several rules that encapsulate its security policy.
- BCRYPT.DLL is supported on Windows Server 2008.
- BCRYPT.DLL operates in FIPS mode of operation only when used with the FIPS approved version of CI.DLL (FIPS 140-2 Cert. #1006) operating in FIPS mode.
- Windows Server 2008 is an operating system supporting a "single user" mode where there is only one interactive user during a logon session.
- BCRYPT.DLL is only in its Approved mode of operation when Windows is booted normally, meaning Debug mode is disabled and Driver Signing enforcement is enabled.
- All users assume either the User or Cryptographic Officer roles.
- BCRYPT.DLL provides no authentication of users. Roles are assumed implicitly. The authentication provided by the Windows Server 2008 operating system is not in the scope of the validation.
- All cryptographic services implemented within BCRYPT.DLL are available to the User and Cryptographic Officer roles.
- BCRYPT.DLL implements the following FIPS-140-2 Approved algorithms.
  - SHA-1, SHA-256, SHA-384, SHA-512 hash (Cert. #753)
  - SHA-1, SHA-256, SHA-384, SHA-512 HMAC (Cert. #412)
  - Triple-DES (2 key and 3 key) in ECB, CBC, and CFB with 8-bit feedback modes (Cert. #656)
  - AES-128, AES-192, AES-256 in ECB, CBC, and CFB with 8-bit feedback mode (Cert. #739)
  - AES-128, AES-192 and AES-256 in CCM (Cert. #756)
  - RSA (RSASSA-PKCS1-v1_5 and RSASSA-PSS) digital signatures (Cert. #357) and X9.31 RSA key-pair generation (Cert. #353).
  - DSA (Cert. #283)
  - ECDSA with the following NIST curves: P-256, P-384, P-521 (Cert. #82).
  - SP800-90 AES-256 based counter mode random number generation algorithm (Vendor-Affirmed)
  - FIPS 186-2 DSA PRNG (Cert. #435).
- BCRYPT.DLL supports the following non-Approved algorithms allowed for use in FIPS mode.
  - Diffie-Hellman (DH) secret agreement (key agreement; key establishment methodology provides between 80 and 150 bits of encryption strength; non-compliant less than 80-bits of encryption strength).
- ECDH with the following NIST curves: P-256, P-384, P-521 (key agreement; key establishment methodology provides between 128 and 256 bits of encryption strength)
- RSA (key wrapping; key establishment methodology provides between 80 and 150 bits of encryption strength; non-compliant less than 80-bits of encryption strength).
- TLS
- SP800-90 Dual-EC DRBG random generator algorithm (non-compliant) – Output can be used for generation of initialization vectors

BCRYPT.DLL also supports the following non FIPS 140-2 approved algorithms, though these algorithms may not be used when operating the module in a FIPS compliant manner.
- AES-128, AES-192 and AES-256 in GCM mode (non-compliant)
- AES-128, AES-192 and AES-256 in GMAC message authentication mode (non-compliant)
- RC2, RC4, MD2, MD4, MD5, HMAC MD5\(^1\).
- DES in ECB, CBC, and CFB with 8-bit feedback
- IKEv1 Key Derivation Functions

The following diagram illustrates the master components of the BCRYPT.DLL module

BCRYPT.DLL was tested using the following machine configurations:

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>x86</td>
<td>Microsoft Windows Server 2008 (x86 version) – Dell SC440 (Intel Pentium D 1.8GHz)</td>
</tr>
<tr>
<td>x64</td>
<td>Microsoft Windows Server 2008 (x64 version) – Dell SC440 (Intel Pentium D 1.8GHz)</td>
</tr>
<tr>
<td>IA64</td>
<td>Microsoft Windows Server 2008 (IA64 version) – HP zx2000 (Intel Itanium2 900MHz)</td>
</tr>
</tbody>
</table>

\(^1\) Applications may not use any of these non-FIPS algorithms if they need to be FIPS compliant. To operate the module in a FIPS compliant manner, applications must only use FIPS-approved algorithms.
Microsoft also affirms that the module maintains validation conformance in the following configurations:

<table>
<thead>
<tr>
<th></th>
<th>Configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>x86</td>
<td>Microsoft Windows Server 2008 SP2 (x86 version)</td>
</tr>
<tr>
<td>x64</td>
<td>Microsoft Windows Server 2008 SP2 (x64 version)</td>
</tr>
<tr>
<td>IA64</td>
<td>Microsoft Windows Server 2008 SP2 (IA64 version)</td>
</tr>
</tbody>
</table>

3 Cryptographic Module Ports and Interfaces

3.1 Ports and Interfaces

3.1.1 Export Functions

The following list contains the functions exported by BCRYPT.DLL to its callers.

- BCryptCloseAlgorithmProvider
- BCryptCreateHash
- BCryptDecrypt
- BCryptDeriveKey
- BCryptDestroyHash
- BCryptDestroyKey
- BCryptDestroySecret
- BCryptDuplicateHash
- BCryptDuplicateKey
- BCryptEncrypt
- BCryptExportKey
- BCryptFinalizeKeyPair
- BCryptFinishHash
- BCryptFreeBuffer
- BCryptGenerateKeyPair
- BCryptGenerateSymmetricKey
- BCryptGenRandom
- BCryptGetProperty
- BCryptHashData
- BCryptImportKey
- BCryptImportKeyPair
- BCryptOpenAlgorithmProvider
- BCryptSecretAgreement
- BCryptSetProperty
- BCryptSignHash
- BCryptVerifySignature

Additionally, BCRYPT.DLL exports crypto configuration functions. They are described in a separate section below for informational purposes.

3.1.2 Data Input and Output Interfaces

The Data Input Interface for BCRYPT.DLL consists of the BCRYPT export functions. Data and options are passed to the interface as input parameters to the BCRYPT export functions. Data Input is kept separate from Control Input by passing Data Input in separate parameters from Control Input.

The Data Output Interface for BCRYPT.DLL also consists of the BCRYPT export functions.

3.1.3 Control Input Interface

The Control Input Interface for BCRYPT.DLL also consists of the BCRYPT export functions. Options for control operations are passed as input parameters to the BCRYPT export functions.
3.1.4 Status Output Interface
The Status Output Interface for BCRYPT.DLL also consists of the BCRYPT export functions. For each function, the status information is returned to the caller as the return value from the function.

3.2 Cryptographic Bypass
Cryptographic bypass is not supported by BCRYPT.DLL.

4 Roles and Authentication
4.1 Roles
BCRYPT.DLL provides User and Cryptographic Officer roles (as defined in FIPS 140-2). These roles share all the services implemented in the cryptographic module. When an application requests the crypto module to generate keys for a user, the keys are generated, used, and deleted as requested by applications. There are no implicit keys associated with a user. Each user may have numerous keys, and each user’s keys are separate from other users’ keys.

4.2 Maintenance Roles
Maintenance roles are not supported by BCRYPT.DLL.

4.3 Operator Authentication
The module does not provide authentication. Roles are implicitly assumed based on the services that are executed.

The OS on which BCRYPT.DLL executes (Microsoft Windows Server 2008) does authenticate users. Microsoft Windows Server 2008 requires authentication from the trusted control base (TCB) before a user is able to access system services. Once a user is authenticated from the TCB, a process is created bearing the Authenticated User’s security token for identification purpose. All subsequent processes and threads created by that Authenticated User are implicitly assigned the parent’s (thus the Authenticated User’s) security token.

5 Services
The following list contains all services available to an operator. All services are accessible to both the User and Crypto Officer roles.

5.1 Algorithm Providers and Properties
5.1.1 BCryptOpenAlgorithmProvider

NTSTATUS WINAPI BCryptOpenAlgorithmProvider( 
    BCRYPT_ALG_HANDLE *phAlgorithm, 
    LPCWSTR pszAlgId, 
    LPCWSTR pszImplementation, 
    ULONG   dwFlags);

The BCryptOpenAlgorithmProvider() function has four parameters: algorithm handle output to the opened algorithm provider, desired algorithm ID input, an optional specific provider name input, and optional flags. This function loads and initializes a CNG provider for a given algorithm, and returns a handle to the opened algorithm provider on success. See http://msdn.microsoft.com for CNG providers. Unless the calling function specifies the name of the provider, the default provider is used. The default provider is the first provider listed for a given algorithm. The calling function must pass the BCRYPT_ALG_HANDLE_HMAC_FLAG flag in order to use an HMAC function with a hash algorithm.

5.1.2 BCryptCloseAlgorithmProvider
NTSTATUS WINAPI BCryptCloseAlgorithmProvider(
    BCRYPT_ALG_HANDLE hAlgorithm,
    ULONG   dwFlags);
This function closes an algorithm provider handle opened by a call to BCryptOpenAlgorithmProvider() function.

5.1.3 BCryptSetProperty

NTSTATUS WINAPI BCryptSetProperty(
    BCRYPT_HANDLE hObject,
    LPCWSTR pszProperty,
    UCHAR   pbInput,
    ULONG   cbInput,
    ULONG   dwFlags);
The BCryptSetProperty() function sets the value of a named property for a CNG object, e.g., a cryptographic key. The CNG object is referenced by a handle, the property name is a NULL terminated string, and the value of the property is a length-specified byte string.

5.1.4 BCryptGetProperty

NTSTATUS WINAPI BCryptGetProperty(
    BCRYPT_HANDLE hObject,
    LPCWSTR pszProperty,
    UCHAR   pbOutput,
    ULONG   cbOutput,
    ULONG   *pcbResult,
    ULONG   dwFlags);
The BCryptGetProperty() function retrieves the value of a named property for a CNG object, e.g., a cryptographic key. The CNG object is referenced by a handle, the property name is a NULL terminated string, and the value of the property is a length-specified byte string.

5.1.5 BCryptFreeBuffer

VOID WINAPI BCryptFreeBuffer(
    PVOID   pvBuffer);
Some of the CNG functions allocate memory on caller’s behalf. The BCryptFreeBuffer() function frees memory that was allocated by such a CNG function.

5.2 Random Number Generation

5.2.1 BCryptGenRandom

NTSTATUS WINAPI BCryptGenRandom(
    BCRYPT_ALG_HANDLE hAlgorithm,
    UCHAR   pbBuffer,
    ULONG   cbBuffer,
    ULONG   dwFlags);
The BCryptGenRandom() function fills a buffer with random bytes. There are two random number generation algorithms:

- BCRYPT_RNG_ALGORITHM. This is the AES-256 counter mode based random generator as defined in SP800-90.
- BCRYPT_RNG_FIPS186_DSA_ALGORITHM. This is the random number generator required by the DSA algorithm as defined in FIPS 186-2.
- BCRYPT_RNG_DUAL_EC_ALGORITHM. This is the non-compliant Dual-EC DRBG based random generator as defined in SP800-90. The output from calls to this PRNG cannot be used for keys; however, it is available for generation of initialization vectors per FIPS 140-2.
When BCRYPT_RNG_USE_ENTROPY_IN_BUFFER is specified in the dwFlags parameter, this function will use the number in the pbBuffer buffer as additional entropy for the random number. If this flag is not specified, this function will use a random number for the entropy.

During the function initialization, a seed is created from the output of an in-kernel random number generator. This RNG, which exists beyond the cryptographic boundary, provides the necessary entropy for the user-level RNGs available through this function.

5.3 Key and Key-Pair Generation

5.3.1 BcryptGenerateSymmetricKey

NTSTATUS WINAPI BCryptGenerateSymmetricKey(
    BCRYPT_ALG_HANDLE  hAlgorithm,
    BCRYPT_KEY_HANDLE  *phKey,
    UCHAR    pbKeyObject,
    ULONG   cbKeyObject,
    UCHAR    pbSecret,
    ULONG   cbSecret,
    ULONG   dwFlags);

The BCryptGenerateSymmetricKey() function generates a symmetric key object for use with a symmetric encryption algorithm from a supplied cbSecret bytes long key value provided in the pbSecret memory location. The calling application must specify a handle to the algorithm provider opened with the BCryptOpenAlgorithmProvider() function. The algorithm specified when the provider was opened must support symmetric key encryption.

5.3.2 BcryptGenerateKeyPair

NTSTATUS WINAPI BCryptGenerateKeyPair(
    BCRYPT_ALG_HANDLE  hAlgorithm,
    BCRYPT_KEY_HANDLE  *phKey,
    ULONG   dwLength,
    ULONG   dwFlags);

The BCryptGenerateKeyPair() function creates a public/private key pair object without any cryptographic keys in it. After creating such an empty key pair object using this function, call the BCryptSetProperty() function to set its properties. The key pair can be used only after BCryptFinalizeKeyPair() function is called.

5.3.3 BcryptFinalizeKeyPair

NTSTATUS WINAPI BCryptFinalizeKeyPair(
    BCRYPT_KEY_HANDLE  hKey,
    ULONG   dwFlags);

The BCryptFinalizeKeyPair() function completes a public/private key pair import or generation. The key pair cannot be used until this function has been called. After this function has been called, the BCryptSetProperty() function can no longer be used for this key pair.

5.3.4 BcryptDuplicateKey

NTSTATUS WINAPI BCryptDuplicateKey(
    BCRYPT_KEY_HANDLE  hKey,
    BCRYPT_KEY_HANDLE  *phNewKey,
    UCHAR    pbKeyObject,
    ULONG   cbKeyObject,
    ULONG   dwFlags);

The BCryptDuplicateKey() function creates a duplicate of a symmetric key object.
5.3.5 BCryptDestroyKey

NTSTATUS WINAPI BCryptDestroyKey(
    BCRYPT_KEY_HANDLE hKey);

The BCryptDestroyKey() function destroys a key.

5.4 Key Entry and Output

5.4.1 BCryptImportKey

NTSTATUS WINAPI BCryptImportKey(
    BCRYPT_ALG_HANDLE hAlgorithm,
    BCRYPT_KEY_HANDLE hImportKey,
    LPCWSTR pszBlobType,
    BCRYPT_KEY_HANDLE *phKey,
    UCHAR pbKeyObject,
    ULONG cbKeyObject,
    UCHAR pbInput,
    ULONG cbInput,
    ULONG dwFlags);

The BCryptImportKey() function imports a symmetric key from a key blob.

hAlgorithm [in] is the handle of the algorithm provider to import the key. This handle is obtained by calling the BCryptOpenAlgorithmProvider function.

hImportKey [in, out] is not currently used and should be NULL.

pszBlobType [in] is a null-terminated Unicode string that contains an identifier that specifies the type of BLOB that is contained in the pbInput buffer. pszBlobType can be one of BCRYPT_KEY_DATA_BLOB and BCRYPT_OPAQUE_KEY_BLOB.

phKey [out] is a pointer to a BCRYPT_KEY_HANDLE that receives the handle of the imported key that is used in subsequent functions that require a key, such as BCryptEncrypt. This handle must be released when it is no longer needed by passing it to the BCryptDestroyKey function.

pbKeyObject [out] is a pointer to a buffer that receives the imported key object. The cbKeyObject parameter contains the size of this buffer. The required size of this buffer can be obtained by calling the BCryptGetProperty function to get the BCRYPT_OBJECT_LENGTH property. This will provide the size of the key object for the specified algorithm. This memory can only be freed after the phKey key handle is destroyed.

cbKeyObject [in] is the size, in bytes, of the pbKeyObject buffer.

pbInput [in] is the address of a buffer that contains the key BLOB to import. The cbInput parameter contains the size of this buffer.

The pszBlobType parameter specifies the type of key BLOB this buffer contains.

cbInput [in] is the size, in bytes, of the pbInput buffer.

dwFlags [in] is a set of flags that modify the behavior of this function. No flags are currently defined, so this parameter should be zero.

5.4.2 BCryptImportKeyPair

NTSTATUS WINAPI BCryptImportKeyPair(
    BCRYPT_ALG_HANDLE hAlgorithm,
    BCRYPT_KEY_HANDLE hImportKey,
    LPCWSTR pszBlobType,
    BCRYPT_KEY_HANDLE *phKey,
    UCHAR pbInput,
    ULONG cbInput,
    ULONG dwFlags);

The BCryptImportKeyPair() function is used to import a public/private key pair from a key blob.
This Security Policy is non-proprietary and may be reproduced only in its original entirety (without revision)
The BCryptEncrypt() function encrypts a block of data of given length. hKey [in, out] is the handle of the key to use to encrypt the data. This handle is obtained from one of the key creation functions, such as BCryptGenerateSymmetricKey, BCryptGenerateKeyPair, or BCryptImportKey.

pbInput [in] is the address of a buffer that contains the plaintext to be encrypted. The cbInput parameter contains the size of the plaintext to encrypt. For more information, see Remarks.

cbInput [in] is the number of bytes in the pbInput buffer to encrypt.

pPaddingInfo [in, optional] is a pointer to a structure that contains padding information. The actual type of structure this parameter points to depends on the value of the dwFlags parameter. This parameter is only used with asymmetric keys and must be NULL otherwise.

pbIV [in, out, optional] is the address of a buffer that contains the initialization vector (IV) to use during encryption. The cbIV parameter contains the size of this buffer. This function will modify the contents of this buffer. If you need to reuse the IV later, make sure you make a copy of this buffer before calling this function. This parameter is optional and can be NULL if no IV is used. The required size of the IV can be obtained by calling the BCryptGetProperty function to get the BCRYPT_BLOCK_LENGTH property. This will provide the size of a block for the algorithm, which is also the size of the IV.

cbIV [in] contains the size, in bytes, of the pbIV buffer.

pbOutput [out, optional] is the address of a buffer that will receive the ciphertext produced by this function. The cbOutput parameter contains the size of this buffer. For more information, see Remarks.

If this parameter is NULL, this function will calculate the size needed for the ciphertext and return the size in the location pointed to by the pcbResult parameter.

cbOutput [in] contains the size, in bytes, of the pbOutput buffer. This parameter is ignored if the pbOutput parameter is NULL.

pcbResult [out] is a pointer to a ULONG variable that receives the number of bytes copied to the pbOutput buffer. If pbOutput is NULL, this receives the size, in bytes, required for the ciphertext.

dwFlags [in] is a set of flags that modify the behavior of this function. The allowed set of flags depends on the type of key specified by the hKey parameter. If the key is a symmetric key, this can be zero or the following value: BCRYPT_BLOCK_PADDING. If the key is an asymmetric key, this can be one of the following values: BCRYPT_PAD_NONE, BCRYPT_PAD_OAEP, BCRYPT_PAD_PKCS1.

5.5.2 BCryptDecrypt

NTSTATUS WINAPI BCryptDecrypt(
    BCRYPT_KEY_HANDLE  hKey,
    PCHAR   pbInput,
    ULONG   cbInput,
    VOID    *pPaddingInfo,
    PCHAR   pbIV,
    ULONG   cbIV,
    PCHAR   pbOutput,
    ULONG   cbOutput,
    ULONG   *pcbResult,
    ULONG   dwFlags);

The BCryptDecrypt() function decrypts a block of data of given length.
hKey [in, out] is the handle of the key to use to decrypt the data. This handle is obtained from one of the key creation functions, such as BCryptGenerateSymmetricKey, BCryptGenerateKeyPair, or BCryptImportKey.
pbInput [in] is the address of a buffer that contains the ciphertext to be decrypted. The cbInput parameter contains the size of the ciphertext to decrypt. For more information, see Remarks.
cbInput [in] is the number of bytes in the pbInput buffer to decrypt.
pPaddingInfo [in, optional] is a pointer to a structure that contains padding information. The actual type of this structure parameter points to depends on the value of the dwFlags parameter. This parameter is only used with asymmetric keys and must be NULL otherwise.
pbIV [in, out, optional] is the address of a buffer that contains the initialization vector (IV) to use during decryption. The cbIV parameter contains the size of this buffer. This function will modify the contents of this buffer. If you need to reuse the IV later, make sure you make a copy of this buffer before calling this function. This parameter is optional and can be NULL if no IV is used. The required size of the IV can be obtained by calling the BCryptGetProperty function to get the BCRYPT_BLOCK_LENGTH property. This will provide the size of a block for the algorithm, which is also the size of the IV.
cbIV [in] contains the size, in bytes, of the pbIV buffer.
pbOutput [out, optional] is the address of a buffer to receive the plaintext produced by this function. The cbOutput parameter contains the size of this buffer. For more information, see Remarks.
If this parameter is NULL, this function will calculate the size required for the plaintext and return the size in the location pointed to by the pcbResult parameter.
 pcbResult [out] is a pointer to a ULONG variable to receive the number of bytes copied to the pbOutput buffer. If pbOutput is NULL, this receives the size, in bytes, required for the plaintext.
dwFlags [in] is a set of flags that modify the behavior of this function. The allowed set of flags depends on the type of key specified by the hKey parameter. If the key is a symmetric key, this can be zero or the following value: BCRYPT_BLOCK_PADDING. If the key is an asymmetric key, this can be one of the following values: BCRYPT_PAD_NONE, BCRYPT_PAD_OAEP, BCRYPT_PAD_PKCS1.

5.6 Hashing and HMAC
5.6.1 BCryptCreateHash

NTSTATUS WINAPI BCryptCreateHash(
    BCRYPT_ALG_HANDLE  hAlgorithm,
    BCRYPT_HASH_HANDLE *phHash,
    PUCHAR   pbHashObject,
    ULONG   cbHashObject,
    PUCHAR   pbSecret,
    ULONG   cbSecret,
    ULONG   dwFlags);

The BCryptCreateHash() function creates a hash object with an optional key. The optional key is used for HMAC type keyed-hash functions.
hAlgorithm [in, out] is the handle of an algorithm provider created by using the BCryptOpenAlgorithmProvider function. The algorithm that was specified when the provider was created must support the hash interface.
pHash [out] is a pointer to a BCRYPT_HASH_HANDLE value that receives a handle that represents the hash object. This handle is used in subsequent hashing functions, such as the BCryptHashData function. When you have finished using this handle, release it by passing it to the BCryptDestroyHash function.
pHashObject [out] is a pointer to a buffer that receives the hash object. The cbHashObject parameter contains the size of this buffer. The required size of this buffer can be obtained by calling the BCryptGetProperty function to get the BCRYPT_OBJECT_LENGTH property. This will provide the size of the hash object for the specified algorithm. This memory can only be freed after the hash handle is destroyed.

pbSecret [in, optional] is a pointer to a buffer that contains the key to use for the hash. The cbSecret parameter contains the size of this buffer. If no key should be used with the hash, set this parameter to NULL. This key only applies to keyed hash algorithms, like Hash-Based Message Authentication Code (HMAC).

cbSecret [in, optional] contains the size, in bytes, of the pbSecret buffer. If no key should be used with the hash, set this parameter to zero.

dwFlags [in] is not currently used and must be zero.

5.6.2 BCryptHashData

NTSTATUS WINAPI BCryptHashData(
    BCRYPT_HASH_HANDLE hHash,
   PUCHAR pbInput,
   ULONG cbInput,
   ULONG dwFlags);

The BCryptHashData() function performs a one way hash on a data buffer. Call the BCryptFinishHash() function to finalize the hashing operation to get the hash result.

5.6.3 BCryptDuplicateHash

NTSTATUS WINAPI BCryptDuplicateHash(
    BCRYPT_HASH_HANDLE hHash,
   BCRYPT_HASH_HANDLE *phNewHash,
   PUCHAR pbHashObject,
   ULONG cbHashObject,
   ULONG dwFlags);

The BCryptDuplicateHash() function duplicates an existing hash object. The duplicate hash object contains all state and data that was hashed to the point of duplication.

5.6.4 BCryptFinishHash

NTSTATUS WINAPI BCryptFinishHash(
    BCRYPT_HASH_HANDLE hHash,
   PUCHAR pbOutput,
   ULONG cbOutput,
   ULONG dwFlags);

The BCryptFinishHash() function retrieves the hash value for the data accumulated from prior calls to BCryptHashData() function.

5.6.5 BCryptDestroyHash

NTSTATUS WINAPI BCryptDestroyHash(
    BCRYPT_HASH_HANDLE hHash);

The BCryptDestroyHash() function destroys a hash object.

5.7 Signing and Verification

5.7.1 BCryptSignHash

NTSTATUS WINAPI BCryptSignHash(
    BCRYPT_KEY_HANDLE hKey,
   VOID *pPaddingInfo,
   PUCHAR pbInput,
   ULONG cbInput,
   PUCHAR pbOutput,
   ULONG cbOutput,
   ULONG *pcbResult,
   ULONG dwFlags);
The BCryptSignHash() function creates a signature of a hash value.

hKey [in] is the handle of the key to use to sign the hash.
pPaddingInfo [in, optional] is a pointer to a structure that contains padding information. The actual type of structure this parameter points to depends on the value of the dwFlags parameter. This parameter is only used with asymmetric keys and must be NULL otherwise.
pbInput [in] is a pointer to a buffer that contains the hash value to sign. The cbInput parameter contains the size of this buffer.
cbInput [in] is the number of bytes in the pbInput buffer to sign.
pbOutput [out] is the address of a buffer to receive the signature produced by this function. The cbOutput parameter contains the size of this buffer. If this parameter is NULL, this function will calculate the size required for the signature and return the size in the location pointed to by the pcbResult parameter.
cbOutput [in] is the size, in bytes, of the pbOutput buffer. This parameter is ignored if the pbOutput parameter is NULL.

The BCryptVerifySignature() function verifies that the specified signature matches the specified hash.

hKey [in] is the handle of the key to use to decrypt the signature. This must be an identical key or the public key portion of the key pair used to sign the data with the BCryptSignHash function.
pPaddingInfo [in, optional] is a pointer to a structure that contains padding information. The actual type of structure this parameter points to depends on the value of the dwFlags parameter. This parameter is only used with asymmetric keys and must be NULL otherwise.
pbHash [in] is the address of a buffer that contains the hash of the data. The cbHash parameter contains the size of this buffer.

5.7.2 BCryptVerifySignature

NTSTATUS WINAPI BCryptVerifySignature(
  BCRYPT_KEY_HANDLE  hKey,
  VOID *pPaddingInfo,
  UCHAR   pbHash,
  ULONG   cbInput,
  UCHAR   pbSignature,
  ULONG   cbSignature,
  ULONG   dwFlags);

The BCryptVerifySignature() function verifies that the specified signature matches the specified hash.

dwFlags [in] is a set of flags that modify the behavior of this function. The allowed set of flags depends on the type of key specified by the hKey parameter. If the key is a symmetric key, this parameter is not used and should be set to zero. If the key is an asymmetric key, this can be one of the following values: BCRYPT_PAD_PKCS1, BCRYPT_PAD_PSS.

5.8 Secret Agreement and Key Derivation

5.8.1 BCryptSecretAgreement

NTSTATUS WINAPI BCryptSecretAgreement(
  BCRYPT_KEY_HANDLE hPrivKey,
  BCRYPT_KEY_HANDLE hPubKey,
  BCRYPT_SECRET_HANDLE *phAgreedSecret,
  ULONG   dwFlags);

The BCryptSecretAgreement() function creates a secret agreement value from a private and a public key. This function is used with Diffie-Hellman (DH) and Elliptic Curve Diffie-Hellman (ECDH) algorithms.
hPrivKey [in] The handle of the private key to use to create the secret agreement value.
hPubKey [in] The handle of the public key to use to create the secret agreement value.
phSecret [out] A pointer to a BCRYPT_SECRET_HANDLE that receives a handle that represents the secret agreement value. This handle must be released by passing it to the BCryptDestroySecret function when it is no longer needed.
dwFlags [in] A set of flags that modify the behavior of this function. This can be zero or the following value: KDF_USE_SECRET_AS_HMAC_KEY_FLAG.

5.8.2 BCryptDeriveKey

NTSTATUS WINAPI BCryptDeriveKey(
    BCRYPT_SECRET_HANDLE hSharedSecret,
    LPCWSTR pwszKDF,
    BCryptBufferDesc *pParameterList,
    UCHAR pbDerivedKey,
    ULONG cbDerivedKey,
    ULONG *pcbResult,
    ULONG dwFlags);

The BCryptDeriveKey() function derives a key from a secret agreement value.
hSharedSecret [in, optional] is the secret agreement handle to create the key from. This handle is obtained from the BCryptSecretAgreement function.
pwszKDF [in] is a pointer to a null-terminated Unicode string that contains an object identifier (OID) that identifies the key derivation function (KDF) to use to derive the key. This can be one of the following strings: BCRYPT_KDF_HASH (parameters in pParameterList: KDF_HASH_ALGORITHM, KDF_SECRET_PREPEND, KDF_SECRET_APPEND), BCRYPT_KDF_HMAC (parameters in pParameterList: KDF_HASH_ALGORITHM, KDF_HMAC_KEY, KDF_SECRET_PREPEND, KDF_SECRET_APPEND), BCRYPT_KDF_TLS_PRF (parameters in pParameterList: KDF_TLS_PRF_LABEL, KDF_TLS_PRF_SEED). pParameterList [in, optional] is the address of a BCryptBufferDesc structure that contains the KDF parameters. This parameter is optional and can be NULL if it is not needed.
pbDerivedKey [out, optional] is the address of a buffer that receives the key. The cbDerivedKey parameter contains the size of this buffer. If this parameter is NULL, this function will place the required size, in bytes, in the ULONG pointed to by the pcbResult parameter.
ccbDerivedKey [in] contains the size, in bytes, of the pbDerivedKey buffer.
pcbResult [out] is a pointer to a ULONG that receives the number of bytes that were copied to the pbDerivedKey buffer. If the pbDerivedKey parameter is NULL, this function will place the required size, in bytes, in the ULONG pointed to by this parameter.
dwFlags [in] is a set of flags that modify the behavior of this function. This can be zero or the following value.

5.8.3 BCryptDestroySecret

NTSTATUS WINAPI BCryptDestroySecret(
    BCRYPT_SECRET_HANDLE hSecret);

The BCryptDestroySecret() function destroys a secret agreement handle that was created by using the BCryptSecretAgreement() function.

5.9 Configuration

These are not cryptographic functions. They are used to configure cryptographic providers on the system, and are provided for informational purposes. Please see http://msdn.microsoft.com for details.

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BCryptAddContextFunction</td>
<td>Adds a function (algorithm or cipher-suite) to a context function list.</td>
</tr>
<tr>
<td>BCryptAddContextFunctionProvider</td>
<td>Adds a provider to a context function provider list.</td>
</tr>
<tr>
<td>BCryptConfigureContext</td>
<td>Configures a context.</td>
</tr>
</tbody>
</table>
BCryptConfigureContextFunction | Configures a context function.
---|---
BCryptCreateContext | Creates a new configuration context.
BCryptDeleteContext | Deletes a configuration context.
BCryptEnumAlgorithms | Enumerates the algorithms for a given set of operations.
BCryptEnumContextFunctionProviders | Enumerates the providers in a context function provider list.
BCryptEnumContextFunctions | Enumerates the functions (algorithms or suites) in a context function list.
BCryptEnumContexts | Enumerates the configuration contexts in the specified table.
BCryptEnumProviders | Returns a list of providers for a given algorithm.
BCryptEnumRegisteredProviders | Enumerates the providers currently registered on the local machine.
BCryptQueryContextConfiguration | Queries the current configuration of a context.
BCryptQueryContextFunctionConfiguration | Queries the current configuration of a context function.
BCryptQueryContextFunctionProperty | Queries the current value of a context function property.
BCryptQueryProviderRegistration | Retrieves registration information for a provider.
BCryptRegisterConfigChangeNotify | This API differs slightly between User-Mode and Kernel-Mode.
BCryptRegisterProvider | Registers a provider for usage on the local machine.
BCryptRemoveContextFunction | Removes a function (algorithm or cipher-suite) from a context function list.
BCryptRemoveContextFunctionProvider | Removes a provider from a context function provider list.
BCryptResolveProviders | This is the main API in Crypto configuration. It resolves queries against the set of providers currently registered on the local system and the configuration information specified in the machine and domain configuration tables, returning an ordered list of references to one or more providers matching the specified criteria.
BCryptSetContextFunctionProperty | Creates, modifies, or deletes a context function property.
BCryptUnregisterConfigChangeNotify | This API differs slightly between User-Mode and Kernel-Mode.
BCryptUnregisterProvider | Removes provider registration information from the local machine.

6 Operational Environment
BCRYPT.DLL is intended to run on Windows Server 2008 in Single User mode as defined in Section 2. When run in this configuration, multiple concurrent operators are not supported. Because BCRYPT.DLL module is a DLL, each process requesting access is provided its own instance of the module. As such, each process has full access to all information and keys within the module. Note that no keys or other information are maintained upon detachment from the DLL, thus an instantiation of the module will only contain keys or information that the process has placed in the module.

7 Cryptographic Key Management
BCRYPT.DLL crypto module manages keys in the following manner.

7.1 Cryptographic Keys, CSPs, and SRDIs
The BCRYPT.DLL crypto module contains the following security relevant data items:
This Security Policy is non-proprietary and may be reproduced only in its original entirety (without revision)

## Security Relevant Data Item

<table>
<thead>
<tr>
<th>Security Relevant Data Item</th>
<th>SRDI Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Symmetric encryption/decryption keys</td>
<td>Keys used for AES or TDES encryption/decryption.</td>
</tr>
<tr>
<td>HMAC keys</td>
<td>Keys used for HMAC-SHA1, HMAC-SHA256, HMAC-SHA384, and HMAC-SHA512.</td>
</tr>
<tr>
<td>DSA Public Keys</td>
<td>Keys used for the verification of DSA digital signatures</td>
</tr>
<tr>
<td>DSA Private Keys</td>
<td>Keys used for the calculation of DSA digital signatures</td>
</tr>
<tr>
<td>ECDSA Public Keys</td>
<td>Keys used for the verification of ECDSA digital signatures</td>
</tr>
<tr>
<td>ECDSA Private Keys</td>
<td>Keys used for the calculation of ECDSA digital signatures</td>

<tr>
<td>RSA Public Keys</td>
<td>Keys used for the verification of RSA digital signatures</td>
</tr>
<tr>
<td>RSA Private Keys</td>
<td>Keys used for the calculation of RSA digital signatures</td>
</tr>
<tr>
<td>DH Public and Private values</td>
<td>Public and private values used for Diffie-Hellman key establishment.</td>
</tr>
<tr>
<td>ECDH Public and Private values</td>
<td>Public and private values used for EC Diffie-Hellman key establishment.</td>
</tr>
</tbody>
</table>

### 7.2 Access Control Policy

The BCRYPT.DLL crypto module allows controlled access to the SRDIs contained within it. The following table defines the access that a service has to each. The permissions are categorized as a set of four separate permissions: read (r), write (w), execute (x), delete (d). If no permission is listed, the service has no access to the SRDI.
Algorithm Providers and Properties

<table>
<thead>
<tr>
<th>Algorithm Providers and Properties</th>

7.3 Key Material
Each time an application links with BCRYPT.DLL, the DLL is instantiated and no keys exist within it. The user application is responsible for importing keys into BCRYPT.DLL or using BCRYPT.DLL's functions to generate keys.

7.4 Key Generation
BCRYPT.DLL can create and use keys for the following algorithms: RSA, DSA, DH, ECDH, ECDSA, RC2, RC4, DES, Triple-DES, AES, and HMAC.
Random keys can be generated by calling the BCryptGenerateSymmetricKey() and BCryptGenerateKeyPair() functions. Random data generated by the BCryptGenRandom() function is provided to BCryptGenerateSymmetricKey() function to generate symmetric keys. DES, Triple-DES, AES, RSA, ECDSA, DSA, DH, and ECDH keys and key-pairs are generated following the techniques given in section 5.2.

7.5 Key Establishment
BCRYPT.DLL can use FIPS approved Diffie-Hellman key agreement (DH), Elliptic Curve Diffie-Hellman key agreement (ECDH), and manual methods to establish keys.

BCRYPT.DLL can use the following FIPS approved key derivation functions (KDF) from the common secret that is established during the execution of DH and ECDH key agreement algorithms:
- BCRYPT_KDF_HASH. This KDF supports FIPS approved SP800-56A (Section 5.8), X9.63, and X9.42 key derivation.
- BCRYPT_KDF_HMAC. This KDF supports FIPS approved IPsec IKE v1 key derivation as specified in FIPS 140-2 Implementation Guidance.
- BCRYPT_KDF_TLS_PRF. This KDF supports FIPS approved SSLv3.1 and TLS v1.0 key derivation as specified in FIPS 140-2 Implementation Guidance.

7.6 Key Entry and Output
Keys can be both exported and imported out of and into BCRYPT.DLL via BCryptExportKey(), BCryptImportKey(), and BCryptImportKeyPair() functions.
Symmetric key entry and output can also be done by exchanging keys using the recipient's asymmetric public key via BCryptSecretAgreement() and BCryptDeriveKey() functions.

Exporting the RSA private key by supplying a blob type of BCRYPT_PRIVATE_KEY_BLOB, BCRYPT_RSAPRIVATE_BLOB, or BCRYPT_RSAPRIVATE_BLOB to BCryptExportKey() is not allowed in FIPS mode.

7.7 Key Storage
BCRYPT.DLL does not provide persistent storage of keys.
7.8 **Key Archival**
BCRYPT.DLL does not directly archive cryptographic keys. The Authenticated User may choose to export a cryptographic key (cf. “Key Entry and Output” above), but management of the secure archival of that key is the responsibility of the user.

7.9 **Key Zeroization**
All keys are destroyed and their memory location zeroized when the Authenticated User calls BCryptDestroyKey() or BCryptDestroySecret() on that key handle.

8 **Self-Tests**
BCRYPT.DLL performs the following power-on (start up) self-tests when DllMain is called by the operating system.
- SHA-1 hash Known Answer Test
- HMAC-SHA-1, HMAC-SHA-256, HMAC-SHA-384, and HMAC-SHA-512 Known Answer Test
- Triple-DES encrypt/decrypt EBC Known Answer Test
- Triple-DES encrypt/decrypt CBC Known Answer Test
- AES-128, AES-192, AES-256 encrypt/decrypt EBC Known Answer Test
- AES-128, AES-192, AES-256 encrypt/decrypt CBC Known Answer Test
- AES-128, AES-192, AES-256 encrypt/decrypt CFB with 8-bit feedback Known Answer Test
- AES-128, AES-192, AES-256 encrypt/decrypt CCM Known Answer Test
- DSA sign/verify test
- RSA sign and verify test
- DH secret agreement Known Answer Test
- ECDSA sign/verify test
- ECDH secret agreement Known Answer Test
- FIPS 186-2 DSA random generator Known Answer Tests
- SP800-90 AES-256 based counter mode random generator Known Answer Test

BCRYPT.DLL performs pair-wise consistency checks upon each invocation of RSA, ECDH, DSA, and ECDSA key-pair generation and import as defined in FIPS 140-2. BCRYPT.DLL also performs a continuous RNG test on each of the implemented RNGs as defined in FIPS 140-2.

In all cases for any failure of a power-on (start up) self-test, BCRYPT.DLL DllMain fails to return the STATUS_SUCCESS status to the operating system. The only way to recover from the failure of a power-on (start up) self-test is to attempt to reload the BCRYPT.DLL, which will rerun the self-tests, and will only succeed if the self-tests passes.

9 **Design Assurance**
The BCRYPT.DLL crypto module is part of the overall Windows Server 2008 operating system, which is a product family that has gone through and is continuously going through the Common Criteria Certification or equivalent under US NIAP CCEVS since Windows NT 3.5. The certification provides the necessary design assurance.
The BCRYPT.DLL is installed and started as part of the Windows Server 2008 operating system.
