Introduction

Purpose

This non-proprietary cryptographic module Security Policy describes the Security Gateway cryptographic module by Check Point Software Technologies Ltd. (Check Point), versions:

- VPN-1 NGX R65 with hot fix HFA 30
- Security Gateway with firewall and vpn Software Blades version R70.1

This security policy describes how the Check Point Security Gateway with firewall and vpn Software Blades and the VPN-1 NGX R65 with hot fix HFA 30 meets the security requirements of FIPS 140-2 and how to configure and operate the module in the FIPS 140-2 Approved mode. This policy was prepared to support the Level 1 FIPS 140-2 validation testing of the module.

The above named versions are alternatively referenced in this document as Check Point Security Gateway, Security Gateway, VPN-1, the module, and the software.

References

This document deals only with operations and capabilities of the module in the technical terms of a FIPS 140-2 cryptographic module. More information is available on the module from the following sources:

- The Check Point website (http://www.checkpoint.com/) contains information on the full line of products from Check Point.

- The NIST Validated Modules website (http://csrc.nist.gov/groups/STM/cmvp/validation.html) provides contact information for answers to technical or sales-related questions regarding the module.
CHECK POINT SOFTWARE BLADES SECURITY GATEWAY

Overview

Check Point Security Gateway is a tightly integrated software solution combining security suite that combines a firewall with sophisticated Virtual Private Network (VPN) technologies and a hardened Operating System (OS). Security Gateway meets the demanding requirements of Internet, intranet, and extranet VPNs by providing secure connectivity to corporate networks, remote and mobile users, branch offices, and business partners. Security Gateway solutions are available on a range of Check Point appliances and the industry’s broadest range of open platforms — meeting the price/performance requirements of any size organization.

- Check Point Security Gateway, the industry’s leading Internet security solution, provides the highest level of security, with access control, content security, authentication, and integrated Network Address Translation.

- Check Point SecurePlatform is a customized and hardened Operating System, with no unnecessary components that could pose security risks. SecurePlatform is pre-configured and optimized to perform its task as a network security device.

Check Point Security Gateway is designed to allow secure access to an organization’s resources to multiple users over an unsecured TCP/IP network. Relying on a hardened, optimized operating system coupled with firewall, it performs all the required security functions and provides the following high-level functionality:

- Screening of all incoming communications to ensure authorized user access.

- Secure, authenticated and encrypted sessions with Clients and subsystems.

- Secure VPN between subsystems.

- Central security administration.

Cryptographic Module

The Check Point Security Gateway cryptographic module is a FIPS 140-2 firmware module. The physical embodiment is multi-chip standalone. Check Point Security Gateway is intended to run on any general purpose PC-class computing platform. Check Point supplies a proprietary, hardened operating system (SecurePlatform) that along with the General Purpose Computer (GPC) containing the required processor(s) provides the cryptographic module’s operational environment. The operational
environment is not modifiable, as it does not allow the module operator to load code or applications that are not part of the FIPS 140-2 validation. Physical security mechanisms are provided by the industry standard computer components and passivation coatings.

Logically, the cryptographic module boundary is composed of the Check Point Security Gateway firmware running on the SecurePlatform Operating System. Physically, the cryptographic boundary of the module is the GPC case, which physically encloses the module. The physical ports, logical interfaces, and FIPS logical interfaces are described in Table 2.

FIPS 140-2 validation testing was performed using the operational environment configurations shown in Chart 1.

CPU, e.g. Intel Celeron®, AMD Opteron®, etc. The CMVP allows vendor porting of a validated firmware cryptographic module and its operating system from the GPC specified on the validation certificate to a GPC which was not included as part of the validation status, as long as no source code modifications are required. The validation status is maintained on the new GPC without re-testing the cryptographic module on the new GPC.

Check Point Power-1, UTM-1 and IAS appliances models are examples of representative GPCs which include 32 bit x86 code-compatible CPUs and custom cases.

The module meets the FIPS 140-2 requirements for an overall Level 1 validation. The following table summarizes the individual FIPS 140-2 requirements sections as outlined in the FIPS 140-2 Derived Test Requirements (DTR) document, as well as the level implemented by the module for each section.

Table 1 –Security Level Implemented Per FIPS 140-2 Test Section

Although the module consists entirely of software, the FIPS 140-2 evaluated platforms are standard Personal Computer enclosures, which each meet the applicable FCC EMI and EMC requirements for business use as defined by 47 Code of Federal Regulations, Part15, Subpart B.

The Security Gateway modules include SNX, a proprietary non-cryptographic protocol that runs over TLS and allows tunneling of IP packets. Using TLS to provide all the cryptographic protection for network data sent via SNX allows a simpler client than a full featured IPSec client. Users can establish TLS-based VPNs to the module using either of two SNX clients:

- SSL Network Extender (a browser based plug-in VPN client)
• SecureClient Mobile (an application based VPN client)

The same CSPs and cryptographic module implementation is used for both VPN protocol sets.

**Module Interfaces**

As a multi-chip standalone module implemented on a General Purpose Computer (GPC), the physical ports of the module include the computer’s network ports, keyboard/mouse ports, USB ports, and serial ports. All of these physical ports are separated into logical interfaces by the module software, and these software logical interfaces are then mapped into FIPS 140-2 logical interfaces, as described in the following table.

<table>
<thead>

</tr>
</tbody>
</table>

*Table 2 – Mapping Standard PC Physical Ports and Logical Interfaces to FIPS 140-2 Interfaces*

The logical interfaces are separated by the UIs that distinguish between data input, data output, control input and status output through the dialogues. Similarly, the module distinguishes between different forms of data, control and status traffic over the Network ports by analyzing the
packets header information and contents. Log files are only utilized for status output.

**Roles and Services**

The module supports three distinct roles: Client User, Local Crypto-Officer, and remote Crypto-Officer roles. It uses digital signatures, pre-shared keys, and passwords for authentication.

The Local Crypto-Officer role is responsible for the installation, minimal configuration, and removal of the Security Gateway. These operations are performed locally using physical access to the PC the module is installed on.

The Remote Crypto-Officer role performs primary configuration of Security Gateway. After authenticating, the Remote Crypto-Officer uses a powerful set of management tools to configure and monitor the module. The remote management session uses TLS to ensure security.

---

**Objects tree contains all objects — for users, hosts, networks and more.**

**Rule base manages Firewall, NAT, QoS, Desktop Security and Web Access policies.**

**Objects list provides easy access to the most commonly used objects.**

**Optional SmartMap module provides a detailed, graphical map of the security.**

---

**Figure 1– Easy to Use Management Tools**

The User role is for clients that are accessing the module from remote locations. These operators can authenticate through IKE using either pre-shared keys or digital certificates. Once authenticated, an encrypted tunnel is established between the Check Point vpn and the client using IPSec. Of note, module can itself act as a User when establishing tunnels to other modules.
Remote Crypto Officer Role

The role of the Remote Crypto-Officer includes refinement of administrative permissions, generation and destruction of keys, user access control and creation of the information database. Each management server (i.e., Remote Crypto-Officer) authenticates to the module through TLS using digital certificates. After authenticating, the Remote Crypto-Officers use Check Point management software to manage the module over the secure TLS session.

Descriptions of the services available to the Crypto Officer role are provided in the table below.

<table>
<thead>
<tr>
<th>Service</th>

</tbody>
</table>
Table 4 – Local Crypto-Officer Services, Descriptions, Inputs and Outputs

User Role

The User role access the module's IPSec and IKE services and the TLS VPN services and authenticates to the module using digital certificates or pre-shared keys (available for IKE).

Service descriptions and inputs/outputs are listed in the following table:

<table>
<thead>
<tr>
<th>Service</th>
<th>Description</th>
<th>Input</th>
<th>Output</th>
<th>CSP</th>
</tr>
</thead>
<tbody>
<tr>
<td>IKE</td>
<td>Access the module’s IKE functionality in order to authenticate to the module and negotiate IKE and IPSec session keys</td>
<td>IKE inputs and data</td>
<td>IKE outputs, status, and data</td>
<td>RSA key pair for IKE (read access); Diffie-Hellman key pair for IKE (read/write access); pre-shared keys for IKE (read access)</td>
</tr>
<tr>
<td>IPSec</td>
<td>Access the module’s IPSec services in order to secure network traffic</td>
<td>IPSec inputs, commands, and data</td>
<td>IPSec outputs, status, and data</td>
<td>Session keys for IPSec (read/write access)</td>
</tr>
<tr>
<td>TLS</td>
<td>Access the module’s TLS functionality in order to authenticate to the module and negotiate TLS session keys in order to secure network traffic</td>

<td>TLS outputs, status, and data</td>
<td>RSA key pair for TLS (read access); session keys for TLS (read/write access)</td>
</tr>
</tbody>
</table>

Table 5 – User Services, Descriptions, Inputs and Outputs
**Authentication Mechanisms**

The module implements password-based authentication, RSA-based authentication, and HMAC-based authentication mechanisms.

<table>
<thead>
<tr>
<th>Authentication Type</th>
<th>Strength</th>
</tr>
</thead>
<tbody>
<tr>
<td>RSA-based authentication (TLS handshake)</td>
<td>RSA encryption/decryption is used to authenticate to the module during the TLS handshake. This mechanism is as strong as the RSA algorithm using a key pair of either 1024, 2048 and 4096 bits. Using 1024 bit key pair (the default), is generally considered equivalent to brute forcing an 80 bit key (i.e., a 1 in 2^80 chance of false positive).</td>
</tr>
<tr>
<td>RSA-based authentication (IKE)</td>
<td>RSA signing/verifying is used to authenticate to the module during IKE. This mechanism is as strong as the RSA algorithm using a key pair of either 1024, 2048 and 4096 bits. Using a 1024 bit key pair (the default), this is generally considered equivalent to brute forcing an 80 bit key (i.e., a 1 in 2^80 chance of false positive).</td>
</tr>
<tr>
<td>Pre-shared key-based authentication (IKE)</td>
<td>SHA-1 HMAC generation/verification is used to authenticate to the module during IKE with pre-shared keys (at least 6 characters in length). Considering the possible field of ASCII characters, the number of potential passwords is 94^6.</td>
</tr>
<tr>
<td>Password-based authentication</td>
<td>Passwords are required to be at least 6 characters in length, a mixture of alphabetic and numeric characters, at least four different characters, and not to use simple dictionary words or common strings such as “qwerty.” Considering only the case sensitive English alphabet and the numerals 0-9 using a 6 digit password with repetition, the number of potential passwords is 62^6.</td>
</tr>
</tbody>
</table>

**Table 6 – Estimated Strength of Authentication Mechanisms**

Each of the authentication mechanisms shown in Table 6 demonstrates that a single, random authentication attempt has less than a 1:1,000,000 chance at success (i.e., a false positive).

Repeated attempts to defeat the authentication mechanisms over a 1-minute period such that there would be a chance for a false positive would require the following attempt rates:

- IKE / HMAC: \( \frac{(94^6)}{(100,000 * 60)} \) = 114,000 attempts per second
- RSA-based: \( \frac{(2^{80})}{(100,000 * 60)} \) = 2*10^17 attempts per second

The cryptographic module cannot process repeated authentication attempts at these frequencies. Additionally, when operating in Approved Mode, the module only allows a maximum of three unsuccessful password-based attempts before imposing a 60 minute lockout period.
The module successfully meets the FIPS 140-2 requirements for strength of authentication for all of its authentication mechanisms.

**Unauthenticated Services**

The cryptographic module does not provide any unauthenticated services. All module services are available only to authenticated operators assuming either a Crypto Officer or a User role.

**Physical Security**

The module meets the physical security requirements for a FIPS 140-2 level 1 firmware module.

**Operational Environment**

The FIPS 140-2 Operational Environment requirements do not apply to this module. The module does not provide a general-purpose operating system nor does it provide a mechanism to load new software.

The cryptographic module is firmware and was tested under the Check Point SecurePlatform™ operating system on the processor types provided by General Purpose Computing platforms in the configurations shown in Chart 1 on Page 5. These processor types are also reflected in the module’s cryptographic algorithm validation certificates.

**Cryptographic Key Management**

Check Point adheres to FIPS-Approved cryptographic standards. Check Point Security Gateways efficient implementation of standard cryptographic algorithms ensures the highest level of interoperability. In addition, the module’s implementations provide some of the fastest system performance available in software.

Security Gateway provides the capability to use TLSv1 to secure management sessions and remote access TLS-based VPN. The module supports IPSEC/ESP for data encryption and IPSEC/ESP for data integrity. It implements all IKE modes: main, aggressive, and quick, using ISAKMP as per the standard.

The Check Point Security Gateway cryptographic module implements the following FIPS-Approved algorithms (NIST-assigned algorithm validation certificate numbers shown in boxed items):

**Data Encryption:**

- Advanced Encryption Standard (AES) in CBC mode (128 or 256 bit keys) – as per NIST FIPS PUB 197
Security Gateway

R65: Certificates #257, #1130 and #1728

- Triple DES (3DES) in CBC modes (168 bit keys) – as per NIST PUB FIPS 46-3 (withdrawn) and NIST Special Publication 800-67

Security Gateway

Certificates #338, #733, #824, #825, #1114 and #1115

Data Packet Integrity:

- HMAC-SHA-1 (20 byte) – as per NIST PUB FIPS 198, RFC 2104 (HMAC: Keyed-Hashing for Message Authentication), and RFC 2404 (The Use of HMAC-SHA-1-96 within ESP and AH).

Security Gateway

Certificates #67, #502, #642, #643, #1003 and #1004

Data Hashing:

- Secure Hash Standard (SHS/SHA-1) – as per NIST PUB FIPS 180-2

Security Gateway

Certificates #332, #890, #1053, #1054, #1511 and #1512

PRNG:

- ANSI X9.31 Implementation

Security Gateway

Certificates #90, #628 and #917

Digital Signatures:

- RSA – PKCS#1 and X9.31
The RSA implementation is used both for signature generation and verification (per PKCS#1), and also for key generation (per ANSI X9.31) when supporting Distributed Key Management (DKM).

The module implements the following protocols permitted for use in a FIPS-Approved mode of operation (per FIPS 140-2 Implementation Guidance 7.1):

Session Security:

- TLS v1.0 – as per RFC 2246
- IPSec
- Secure Socket Layer (SSL) v3.1 – as per the Transport Layer Security Working Group draft

Key Agreement / Key Establishment:

Encryption strength is determined by using the equation provided in FIPS 140-2 Implementation Guidance 7.5 and NIST Special Publication 800-57, Part 1. Encryption strength is a function of the key size implemented.

- In FIPS mode the Diffie-Hellman key agreement methodology implemented by the module (used by IKE) provides between 112 and 128 bits of encryption strength (only DH Groups 14 to 18 shall be used).
- The RSA key wrapping methodology (used by TLS), provides between 80 bits and 150 bits of encryption strength.

In addition to the FIPS-Approved algorithms, the Check Point Security Gateway provides the following non FIPS-approved algorithms:

- CAST (40 or 128 bit keys)
- HMAC-MD5 (16 bytes) – as per RFC 2104 (HMAC: Keyed-Hashing for Message Authentication) and RFC 2403 (The Use of HMAC-MD5-96 within ESP and AH).
- MD5
- DES

The following is a list of the Critical Security Parameters (CSPs) implemented by the module:

Table 7 – Listing of the Module’s CSPs

The Local Crypto-Officer passwords are used to authenticate the Local Crypto-Officer to the CLI. Additionally, these passwords are used to switch CLI modes and to access the bootloader. These passwords are configured by the local Crypto-Officer over the CLI or by the Remote Crypto-Officer over an authenticated, encrypted management session.

¹ When in FIPS mode only Diffie-Hellman Group 14 to 18 shall be used. This provides between of 112 and 128 bits of encryption strength.
² TLS is used for SIC, SSL Network Extender and SecureClient Mobile
These passwords are stored on the module’s hard drive, and can be zeroized by changing the password or reformatting the hard drive.

The RSA key pair for remote management sessions is generated externally by the management software. This key pair is loaded onto the module during the setup of secure communications with a management station over a secure TLS session. This key pair is stored on the module’s hard drive and can be zeroized by reformatting the hard drive containing the module’s software or re-initializing SIC.

The RSA key pair used by IKE and remote access TLS-based VPN can be generated either external to the module by the management software or internally by the module through Distributed Key Management (DKM). When generated externally, this key pair is loaded onto the module over a secure TLS session established between the module and the management software. When DKM is used, this key pair is generated internally by the module. The Local Crypto Officer configures the module for either internal key generation or to import external keys from the management station. This key pair is stored on the module’s hard drive in plaintext and can be zeroized by reformatting the module’s hard drive containing the module’s software. Additionally, it can be overwritten by generating a new RSA key pair.

Pre-shared keys are input into the module over an encrypted management session. These keys are used during IKE for authentication. The pre-shared key configuration information is stored on the module’s hard drive and can be zeroized by reformatting the hard drive containing the module’s software. Additionally, it can be overwritten by changing the pre-shared key.

Diffie-Hellman (DH) key pairs are generated during IKE for use for key exchange during IKE. These are ephemeral key pairs. The Diffie-Hellman public parameters are generated externally by the management software. These parameters are loaded onto the module over a secure TLS session established between the module and the management software. These parameters are stored on the module’s hard drive, and can be zeroized by reformatting the hard drive containing the module’s software or by generating a new set of DH public parameters.

Session keys for IPSec are ephemeral keys established for IPSec connections. These keys are negotiated during IKE as part of the DH key exchange. They are generated as needed by an SA and are only stored in volatile memory. These keys can be zeroized by powering down the module.

Session keys for TLS-based VPNs are ephemeral keys established as part of the TLS handshake protocol. They are generated as needed and
are only stored in volatile memory. These keys can be zeroized by powering down the module.

Session keys for management session are established by the TLS handshake protocol. These keys are used to encrypt management session and are generated as needed by the TLS handshake. These keys are stored in volatile memory as well as cached to disk for possible reuse. The keys in volatile memory can be zeroized by powering down the module. The keys cached to disk can be zeroized by reformatting the hard drive containing the module's software.

The X9.31 pseudo-random number generator (PRNG) keys are generated by the module using entropy gathered from `/dev/random` device. The entropy used to generate these keys is cached to the module’s hard drive and are used by the X9.31 PRNG.

Management Workstation

The Check Point management workstation, which is external to this module, generates RSA keys using ANSI X9.31. Those keys are used to digitally sign messages that are verified by the module when the management workstation (the Remote Crypto Officer) sends it commands. The management workstation’s implementation of RSA has been issued NIST RSA algorithm certificate #67.

Self-Tests

The module performs a set of self-tests in order to ensure proper operation in compliance with FIPS 140-2. These self-tests are run during power-up (power-up self-tests) or when certain conditions are met (conditional self-tests).

Power-up Self-tests:

- Firmware Integrity Tests: The module checks the integrity of its various components using a 64 bit error detection code (EDC) calculated by the cphash binary when FIPS mode is enabled.

- Cryptographic Algorithm Known Answer Tests (KATs): KATs are run at power-up for AES, DES, RSA, and Triple-DES encryption/decryption, pseudo-random number generation, SHA-1 hashing, and HMAC with SHA-1 calculation.
  - AES-CBC KAT
  - DES-CBC KAT
  - Triple-DES-CBC KAT
  - PRNG KAT
- RSA (encrypt/decrypt) and (sign/verify) KAT tests
- SHA-1 KAT
- SHA-1 HMAC KAT

- **Bypass Mode Test:** The module performs SHA-1 check value verification to ensure the policy files have not been modified.

**Conditional Self-tests:**

- **Continuous Random Number Generator Test:** This test is constantly run to detect failure of the module’s random number generator

- **RSA pair-wise consistency test:** This test is run by the module whenever RSA key pairs are generated internally to support Distributed Key Management to verify that a valid key pair was created.

- **Bypass Mode Test:** The module performs SHA-1 check value verification to ensure the policy files have not been modified.

If any of the kernel module KATs fail, the system enters the kernel panic state. If any one of the service KATs fails, that service halts and the system enters the error state. If the KATs are passed (by both the kernel modules and the services), the success is logged to the Check Point log. If the power-up software integrity check fails, the system enters the integrity check failure state, halts, and has to be restarted. If the software integrity check passes, the event is logged to the Check Point log. If the continuous RNG test fails, the system reboots. All errors are logged to the Check Point logs.

When the module enters the error state, all cryptographic services and data output for the problem service is halted until the error state is cleared. Restarting the module or the failed service can clear the error state.

**Design Assurance**

Check Point uses a hybrid configuration management system for its products and documentation management needs. Both CVS and Rational® ClearCase® are used for configuration management of product source code releases. These software applications provide access control, versioning, and logging capabilities for tracking the components included in the various Check Point products. Manual configuration management controls are utilized for the associated product documentation. A formal process has been implemented whereby a log is kept of all product documentation and updates. Product documentation releases are tied to
versions of the cryptographic module and source code build releases through this log.

Subversion is used to provide configuration management and archival for the module’s FIPS 140-2 documentation. This document database application provides access control, versioning, and logging for documents created in support of FIPS 140-2 validation testing efforts.

**Mitigation of Other Attacks**

The module is designed to meet the overall FIPS 140-2 level 1 requirements and provides the standard level of security that comes with meeting those requirements. It does not provide mitigation against other attacks.
SECURE OPERATION

Check Point Security Gateway meets Level 1 requirements for FIPS 140-2. The sections below describe how to place and keep the module in FIPS-approved mode of operation.

FIPS Mode Configuration

Local Crypto-Officer Configuration Steps

The Local Crypto-Officer must perform the following operations during installation and initialization of the module in order to enable the FIPS mode of operation.

Note: These instructions also apply if the Local Crypto-Officer is migrating from previous module versions to NGX R65 with hot fix HFA 30 or higher. The Local Crypto-Officer must reinstall and reinitialize the module as per these instructions. The HFA code is loaded during initialization before FIPS mode is enabled as once the module is placed in FIPS mode no additional code can be loaded.

The vpn module include support for Diffie-Hellman Groups up to Group 14 (2048 bit modulus) key sizes. Additional Diffie-Hellman Groups 15-18 (3072 bits to 8192 bits) must be configured during the initialization process by the Local Crypto-Officer before beginning the initialization of the module. The procedure for enabling the additional groups is obtainable from Check Point support SK27054 on the Check Point web. 1

The system time clocks of the module platform, the management station, and any other trusted systems must all be synchronized.

1. Install the SecurePlatform operating system. The module automatically reboots the system once this is completed.

   Note: when installing onto some computing platforms, it will be necessary to load the software from a temporarily-connected USB CD-ROM or via the network interface by using FTP.

2. Login to the console using the default Local Crypto-Officer password. The module will immediately request that this password be changed.

3. At the command prompt, run the following command to begin configuration of the module.

   sysconfig

   The following will be performed via the menus displayed when “sysconfig” is run.
a. Perform the network configuration, date and time configuration, and the licensing configuration.

b. When prompted to select Check Point software to install on top of the operating system, for R65 with HFA 30 select “VPN-1 Power” and for R70.1 select “Security Gateway”.

c. Select a distributed (not standalone) installation.

d. Continue through the rest of the configuration until the sysconfig command finishes.

4. Reboot the module.

5. Login to the console.

6. Switch to expert mode.

8. Edit `/boot/grub/grub.conf` and remove all of the lines below and including the “title Start in maintenance mode” line.

10. Copy `/etc/cpshell/cpshell.cfg` to `/etc/cpshell/cpshell.cfg.bak`.

11. Edit `/etc/cpshell/cpshell.cfg` and remove the line beginning with “patch”.

12. Save `/etc/cpshell/cpshell.cfg`.

13. Copy `/etc/cpshell/fips.cfg` to `/etc/cpshell/fips.cfg.bak`.

14. Edit `/etc/cpshell/fips.cfg` and add the following line.

   ```
   expert 0 1 “expert” “Switch to expert mode”
   ```

15. Save `/etc/cpshell/fips.cfg`.

17. Edit `$CPDIR/conf/sic_policy.conf` and remove all of the following keywords:

   ```
   sslca_rc4
   sslca_rc4_comp
   ```
asym_sslca_rc4
asym_sslca_rc4_comp
none
sslca_clear
ssl
sslc
fwa1
skey
fwn1
skey2
ssl_opsec
fwn1_opsec

Note: If removal of these terms results in the column being blank (columns are delimited by a semi-colon (";")) then comment the line out or remove it. If these words are followed by a comma (", "), then remove it as well.

18. Save $CPDIR/conf/sic_policy.conf.

19. For Security Gateway with firewall and vpn Software Blades only install the R70.1 HFA-01 patch. (This patch is not required or applicable for the VPN-1 NGX R65 with hot fix HFA-30)

20. Exit expert mode.

21. Switch the module to FIPS mode by entering the following command:

    fips on

22. Reboot.

Running the “fips on” command disables SSH, disables the Web UI, removes support for SSLv3 from SIC (i.e. only TLS is supported), enables Local Crypto-Officer account lockout of 60 minutes after 3 failed authentication attempts, disables remote installation daemon, and removes access to the fw, fwm, and vpn command line utilities.

The Local Crypto-Officer must not switch out of FIPS mode or disable the software integrity check.
**Management Station Configuration Steps**

On the Management Station configure support for additional Diffie-Hellman Groups 15-18, Follow the instructions found in SK27054 for defining the moduli for these Diffie-Hellman Groups in the product database.

In order for the external management station to operate correctly with the module running in FIPS mode, the following commands must be run on the management station. Also, the time clock on the management station should be synchronized with the module platform as well as any other trusted systems.

1. If the Check Point services are running, execute the following command to stop all Check Point services.
   
   ```
   cpstop
   ```

2. Copy `$CPDIR/conf/sic_policy.conf` to `$CPDIR/conf/sic_policy.conf.bak`.

3. Edit `$CPDIR/conf/sic_policy.conf` and remove all of the following keywords:
   
   ```
   sslca_rc4
   sslca_rc4_comp
   asym_sslca_rc4
   asym_sslca_rc4_comp
   none
   sslca_clear
   ssl
   sslclear
   fwa1
   skey
   fwn1
   skey2
   ssl_opsec
   fwn1_opsec
   ```

   **Note:** If removal of these terms results in the column being blank (columns are delimited by a semi-colon (";")) then comment the line
out or remove it. If these words are followed by a comma (', '), then remove it as well.

4. Run the following command to enable only TLSv1 for management sessions.

   `ckp_regedit -a "Software\CheckPoint\SIC" FIPS_140 -n 1`

5. If the Check Point services were stopped in step 1, restart them by entering the following command.

   `cpstart`
Remote Crypto-Officer Configuration Guidelines

The Remote Crypto-Officer must follow the following guidelines for configuring the modules services.

Authentication during IKE and TLS must employ pre-shared keys or digital certificates. Additionally, only the following FIPS-approved algorithms may be used by IPSec, IKE and TLS:

**Data Encryption**
- Triple-DES
- AES

**Data Packet Integrity**
- HMAC with SHA1

**Authentication**
- Certificates
- Pre-shared keys

**Key Exchange**
- Diffie-Hellman Group 1 (768-bits) provides only 57 bits of encryption strength. Only Diffie-Hellman groups 14 or higher, providing 112 or more bits of encryption strength shall be used.

The following figures contain screen-shots that illustrate the module’s FIPS mode settings:
Figure 2 – Only FIPS-Approved Algorithms may be used with IKE
Figure 3 – Only Pre-Shared Keys or Digital Certificates may be used to Authenticate Clients
Figure 4 – Only FIPS-Approved Algorithms may be used with IKE
Figure 5 – Only FIPS-Approved Algorithms may be used with IPSec
Figure 6 – Only FIPS-Approved Algorithms may be used with TLS
Figure 7 – Only FIPS-Approved Algorithms may be used with TLS

Figure 9 – Configuring the module to generate RSA keys with DKM on a per-certificate basis
Crypto-Officer Guidance

The Crypto-Officer is responsible for installation and initialization of the module, configuration and management of the module, and removal of the module. More details on how to use the module can be found in the Check Point NG user manuals.

The Crypto-Officer receives the module in a shrink wrapped package containing a CD-ROM with the VPN-1 or Security Gateway installation media and user documentation. The Crypto-Officer should examine the package and shrink wrap for evidence of tampering. Tamper-evidence includes tears, scratches, and other irregularities in the packaging.

Before the installation of the module, there is no access control provided by the module. Therefore, the Crypto-Officer must maintain control of the installation media.

During installation, the Crypto-Officer boots a standard PC from the CD-ROM containing the module’s software. The Crypto-Officer will walk through a series of steps, and must follow the directions above to properly configure the module for FIPS 140-2 compliance.

The Local Crypto-Officer password for the module is a default after installation. Before this is changed, the Crypto-Officer should maintain control of the module. This must be changed immediately upon logging into the module after installation.

The Crypto-Officer must establish the SIC configuration after logging into the module for the first time. Once this has been completed, the module has been adequately initialized and can be managed from the management server.

Management

Once initialization of the module has been completed, the Crypto-Officer should manage the module using the remote management server. Through this server, the Crypto-Officer is able to configure policies for the module. These policies determine how the firewall and VPN services of the module will function.

The Crypto-Officer is responsible for maintaining the module. Besides management of the module, this involves monitoring the module’s logs. If unusual or suspicious activity is found, the Crypto-Officer must take the module offline and investigate.

If the module consistently malfunctions or otherwise repeatedly enters an error state, the Crypto-Officer should contact the manufacturer.
Termination

At the end of the life cycle of the module, the Crypto-Officer should reformat the hard drive containing the module’s software. This will zeroize all keys and other CSPs.

User Guidance

The User access the module’s VPN functionality as an IPSec client or as a remote access TLS-based VPN client. Although outside the boundary of the module, the User should be careful not to provide authentication information and session keys to other parties.
