1 Module Overview

The S&C IntelliCom WAN® 1720-Series Wireless Mesh Node: IntelliCom WAN 1720 (HW P/N IntelliCom WAN 1720, Version 1.0; FW Version 1.1.0.0) (hereafter referred to as the cryptographic module) is a multi-chip standalone module.

The boundary of the cryptographic module is the outer enclosure.

Note: The antennas are not a part of the cryptographic boundary.

Figure 1 – Image of the Cryptographic Modules: IntelliCom WAN 1720
Figure-2 (below) depicts a block diagram of the cryptographic module’s hardware components, with the cryptographic boundary shown in red. The major blocks of the cryptographic module’s hardware are:

- Memory: RAM, Flash and EEPROM
- CPU
- Network: Ethernet, Wireless
- Serial Port: Not accessible
- USB: Not used
- LEDs

This cryptographic module comes in one model, the IntelliCom WAN 1720 which is meant for outdoor operations. Upon power up, this cryptographic module comes up in FIPS operational mode upon verifying all the security functions of the cryptographic module.

This cryptographic module allows user management and control data to flow thorough ethernet and wireless interfaces. It is necessary to configure the end to end AES key prior to data flow to have the data encrypted. All unencrypted user data traffic entering through the ethernet is encrypted by CPU hardware by the user configured AES key. Only encrypted user data is sent or received over the wireless interface. The wireless interface is never used to terminate user traffic. Management traffic entering and leaving the ethernet and wireless interfaces are always encrypted by TLS. Control traffic may or may not be encrypted.
1.1 Information flow among various hardware elements in IntelliCom WAN 1720 Mesh nodes

The cryptographic module allows to be powered through A/C or D/C power.

EEPROM stores node information like the type of the node, serial number and network devices’ (ethernet and wireless) mac addresses. CPU can read and write (program & reprogram) the information on the EEPROM.

Flash stores the loader, firmware and configuration of the node. CPU can read and write (program & reprogram) the storage on the flash.

USB port is currently disabled and doesn’t participate in any activity on the nodes.

Serial port gives console access to the cryptographic module. Serial port is not accessible on FIPS nodes.

LEDs consist of status and ethernet activity LEDs. CPU controls status LEDs to show status about the Power, System, and wireless interface. Ethernet hardware updates ethernet activity LEDs.
RAM is used to load and run the firmware and store and forward data to and from ethernet and wireless interfaces. RAM can be accessed by the CPU for program execution and data storage and retrieval. RAM is accessed by ethernet to store packets received from the ethernet ports and for retrieval of packets that will be sent out on those ports. RAM is accessed by wireless interfaces to store packets received from the ethernet ports and for retrieval of packets that will be sent out on those interfaces. Management, control, and user data traffic enter and leave through ethernet and wireless interfaces. CPU performs required authentication, encryption, and decryption on the traffic as necessary.

Reset button allows for power cycle and factory default functions.

Cryptographic module services are described in Section 6 below.
2 Security Level

The cryptographic module meets the overall requirements applicable to Level 2 security of FIPS 140-2.

3 Modes of Operation

3.1 FIPS Approved Mode of Operation

The cryptographic module only provides a FIPS Approved mode of operation, comprising all services described in Section 6 below.

The cryptographic module will enter FIPS Approved mode following successful power up initialization. The cryptographic module will automatically indicate the FIPS Approved mode of operation by the ‘status’ LED turning solid green; FIPS mode can be confirmed by the solid green ‘status’ LED or through IntelliComView (NMS) management software showing “FIPS” on the cryptographic module icon as shown in Figure 3.

![Figure 3- IntelliComView FIPS mode icon](image)

This cryptographic module doesn’t operate in Non-FIPS mode. Should FIPS mode fail, this cryptographic module sits in an error state shown by flashing ‘status’ LED. IntelliComView (NMS) will not be able to login into the module and status would be represented as shown in Figure 4.

![Figure 4 – IntelliComView FIPS failure or Node down icon](image)
### 3.2 Approved and Allowed Algorithms

The cryptographic module supports the following FIPS Approved algorithms.

**Table 2 – FIPS Approved Algorithms Used in Current Module**

5 Identification and Authentication Policy

5.1 Assumption of Roles

The cryptographic module supports four (4) distinct roles; NMS Admin (referred to as Crypto-Officer), NMS Guest (referred to as User), CLI kepolo, and Peer. The cryptographic module enforces the separation of roles by using separate sessions per authentication. There is one session created per authentication and no change of role is allowed within the same session. The cryptographic module only allows one session for NMS access either as an ‘admin’ or as a ‘guest’ at a given time.

<table>
<thead>
<tr>
<th>Role</th>

</thead>
<tbody>
<tr>
<td>Username and Password – 5 characters minimum.</td>
<td>Each character could be from a set of upper &amp; lower case alphabets (26 each), numbers (10), other displayable characters (12+) which totaling 64+. The probability that a random attempt will success or a false acceptance will occur is 1/(64^5) which is 1/(2^30) which is less than 1/1,000,000. If the authentication takes 2 seconds per attempt, less than 30 chances are possible in a minute. The probability of successfully authenticating to the cryptographic module within one minute is 30 * 1/(64^5) which is (2^5) * 1/(2^30) which is less than 1/100,000.</td>
</tr>
<tr>
<td>RSA 1024</td>

6.4 Definition of Critical Security Parameters (CSPs)

The cryptographic module contains the following CSPs:

Table 11 – Private Keys and CSPs

<table>
<thead>
<tr>
<th>Key Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>End to End PSK</td>

<td>Used during TLS connection</td>
</tr>
<tr>
<td></td>
<td></td>
<td>establishment</td>
</tr>
</tbody>
</table>
NMS Admin Password | PIN minimum 5 ASCII | Used for authenticating NMS Admin role
NMS Guest Password | PIN minimum 5 ASCII | Used for authenticating NMS Guest role
CLI kepolo Password | PIN minimum 5 ASCII | Used for authenticating CLI read only user
TLS Confidentiality Keys | AES 128 | Used for encryption of TLS traffic
HMAC Keys | HMAC 128 | Used for data integrity checks in TLS

### 6.5 Definition of Public Keys

The cryptographic module contains the following public keys:

<table>
<thead>
<tr>
<th>Key Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>S&amp;C CA Key</td>
<td>RSA 1024</td>

<td>Used for management traffic encryption</td>
</tr>
<tr>
<td>S&amp;C Build Key</td>
<td>RSA 1024</td>
<td>Used to verify firmware load image</td>
</tr>
</tbody>
</table>

### 6.6 Definition of CSPs Modes of Access

Table 13 defines the relationship between access to CSPs and the different cryptographic module services. The modes of access shown in the table are defined as:

- **G** = Generate: The cryptographic module generates the CSP.
- **R** = Read: The cryptographic module reads the CSP. The read access is typically performed before the cryptographic module uses the CSP.
- **W** = Write: The cryptographic module writes the CSP. The write access is typically performed after a CSP is imported into the cryptographic module, or the cryptographic module generates a CSP, or the cryptographic module overwrites an existing CSP.
- **Z** = Zeroize: The cryptographic module zeroizes the CSP.
**Table 13 – CSP Access Rights within Roles & Services**

</tbody>
</table>
7 Operational Environment

The FIPS 140-2 Area 6 Operational Environment requirements are not applicable because the cryptographic module does not contain a modifiable operational environment.
8 Security Rules

The cryptographic module’s design corresponds to the cryptographic module’s security rules. This section documents the security rules enforced by the cryptographic module to implement the security requirements of FIPS 140-2 for a Level 2 cryptographic module.

8.1 Module Rules

1. The cryptographic module shall provide four distinct operator roles. These are NMS Admin, NMS Guest, Peer, and CLI kepolo.

2. The cryptographic module shall provide role-based or identity-based authentication.

3. The cryptographic module shall clear previous authentications on power cycle.

4. The cryptographic module shall provide a separate session per user authentication.

5. The cryptographic module shall clear previous authentications upon the authenticated user leaving the session.

6. The cryptographic module shall not allow changes in role in any session.

7. When the cryptographic module has not been placed in a valid role, the operator shall not have access to any cryptographic services.

8. The cryptographic module shall perform the following tests:

   A. Power up Self-Tests

      1. Cryptographic algorithm tests
         a. AES Encrypt and Decrypt Known Answer Test, for Cavium hardware
         b. AES 128 Encrypt and Decrypt Known Answer Test, for OpenSSL (TLS) crypto library
         c. RSA Sign/Verify Known Answer Test
         d. SHA-1 Known Answer Test
         e. SHA-512 Known Answer Test
         f. HMAC-SHA-1 Known Answer Test
         g. RNG Known Answer Test

      2. Firmware Integrity Test – 32-bit CRC

   B. Critical Functions Tests

      1. Certificate Validity test

   C. Conditional Self-Tests

      1. RNG input test – done during every power up
      2. ANSI X9.31 RNG Continuous Test – whenever a RNG value is requested
      3. Firmware Signature Verification – 1024-bit RSA signature verification upon load
9. The operator shall be capable of commanding the cryptographic module to perform the power up self-test by re-cycling power or rebooting the cryptographic module.

11. Data output shall be inhibited during key generation, self-tests, zeroization, and error states.

12. Status information does not contain CSPs or sensitive data that if misused could lead to a compromise of the cryptographic module.

13. There are no restrictions on which keys or CSPs are zeroized by the zeroization service.

14. The cryptographic module supports concurrent operators and maintains separation between them.

15. The cryptographic module does not support a maintenance interface or role.

16. The cryptographic module does not support manual key entry.

17. The cryptographic module does not have any external input/output devices used for entry/output of data.

18. The cryptographic module does not enter or output plaintext CSPs.

19. The cryptographic module does not output intermediate key values.

20. The cryptographic module does not support generating or regenerating node certificates.

21. The cryptographic module does not allow direct user access to the system through wireless interfaces.

### 8.2 Vendor Imposed Security Rules

This section documents the security rules required by the Vendor to maintain the cryptographic module.

1. CO should change the default ‘NMS Admin’ password before any data operations.

2. CO should set ‘End to End PSK’ before any data operations.

3. Enforce a strong password policy and change them on a regular basis.

4. Inspect the cryptographic module regularly for damage, intrusion, and tampering.

5. Ensure that only authorized personnel access the cryptographic module.

6. Use a trusted host for IntelliComView NMS that manages the cryptographic module.

7. Upgrade the cryptographic module only with approved firmware. Note: To maintain validation, only validated firmware should be loaded. Loading non-validated firmware will invalidate the cryptographic modules validation.
9 Physical Security Policy

9.1 Physical Security Mechanisms

The multi-chip standalone cryptographic module is production quality containing standard passivation. S&C IntelliCom WAN 1720 is housed in metal enclosures. Both enclosures are opaque within the visible spectrum and have been designed to satisfy FIPS 140-2 Level 2 physical security requirements. Models IntelliCom WAN 1720 requires tamper evident labels to be applied. It is the responsibility of the Crypto-Officer to apply the labels on the S&C equipment prior to deployment and field use. The labels are serialized. The Crypto-Officer should make a record of the S&C serial number and the corresponding label serial numbers used. The application of the labels is described in Figures 5 – 7.

Figure 5 – Location of Tamper Evident Labels (2 Total) for the IntelliCom WAN 1720

Prior to applying the labels, the areas at which the label will be applied must be cleaned using isopropyl alcohol (99%) and a lint-free cloth to assure optimum bonding of the label to the surface. It is recommended that the labels be applied at a temperature > 50 °F.
For the IntelliCom WAN 1720, apply the two labels at the locations detailed in Figures 6 – 7.

Figure 6 – Location of Bottom Side Tamper Evident Label on the IntelliCom WAN 1720

Apply label to bottom edge of back cover. Label should wrap down to cover seam and attach to main enclosure body.
The labels on each deployed unit should be periodically (every 3 months) inspected for evidence of tampering and for physical integrity. If the labels appear to have been tampered with, consult with customer support to determine if the cryptographic module should be zeroized and returned to the vendor for replacement.
10 Mitigation of Other Attacks Policy

The cryptographic module has not been designed to mitigate any attacks outside of the scope of FIPS 140-2.
