1. **Introduction**

1.1. **Scope**

This Security Policy specifies the security rules under which the µMACE must operate. In addition to the security requirements derived from FIPS 140-2 are those imposed by Motorola. These rules, in total, define the interrelationship between the:

- Module Operators,
- Module Services, and
- Critical Security Parameters (CSPs).

1.2. **Definitions**

1.3. **Overview**

The µMACE provides secure key management and data encryption for the Motorola Solutions CRYPTR Micro which is used in the following broadband and LTE Systems:

- ES400 phone
- AME2000 line of secure phones
- MCC7100 Dispatch Console

1.4. **µMACE Implementation**

The µMACE is implemented as a single chip cryptographic module as defined by FIPS 140-2.
1.5. µMACE Hardware / Firmware Version Numbers

The µMACE has the following FIPS validated hardware and firmware version numbers:

Table 1: FIPS Validated Version Numbers

<table>
<thead>
<tr>

1.6. µMACE Cryptographic Boundary

The µMACE in the block diagram below provides data security services required by the CRYPTR Micro product. The module is a single µMACE processor with the set of interfaces shown in the diagram below.

![Figure 1: µMACE Block Diagram](image-url)
The Crypto Boundary is drawn around the µMACE as shown below.

**Figure 2: µMACE**
1.7. Ports and Interfaces

The µMACE provides the following physical ports and logical interfaces:

2. FIPS 140-2 Security Levels

The µMACE can be configured to operate at FIPS 140-2 overall Security Level 2. The table below shows the FIPS 140-2 Level of security met for each of the eleven areas specified within the FIPS 140-2 security requirements.

<table>

3. **FIPS 140-2 Approved Operational Modes**

The µMACE can be configured to operate in a FIPS 140-2 Approved mode of operation and a non-FIPS Approved mode of operation. CSPs cannot be shared between FIPS Approved mode and non-FIPS Approved mode. When transitioning between FIPS Approved mode and non-FIPS Approved mode the Operator shall zeroize all CSPs.

The Version Query service can be used to verify the firmware version matches an approved version listed on NIST’s website:  http://csrc.nist.gov/groups/STM/cmvp/validation.html

3.1. **Configuration Settings for operation at FIPS 140-2 overall Security Level 2**

Documented below are the actions and configuration settings required for the module to be used in a FIPS 140-2 Approved mode of operation at overall Security Level 2.

1. Disable Clear Key Import. The Module Configuration service is used to configure this parameter in the module. When this configuration setting is disabled, clear key import will be disallowed.
2. Disable Clear Key Export. The Module Configuration service is used to configure this parameter in the module. When this configuration setting is disabled, clear key export will be disallowed.
3. Disable Key Loss Key (KLK). The Module Configuration service is used to configure this parameter in the module.
4. Disable Red Keyloading. The Module Configuration service is used to configure this parameter in the module. When this configuration setting is disabled, red keyloading via the KVL interface will be disallowed.
5. Only Approved and Allowed algorithms may be utilized. The module supports the following Approved algorithms:
   - AES-256 8-bit CFB8 (Cert. #1876) – used for symmetric encryption / decryption of keys and parameters stored in the internal database
   - AES-256 ECB (Cert. #1876) - for use with key wrap
   - AES-256 CBC (Cert. #1876) - for firmware upgrades
   - AES256 CTR (Cert. #2146)
   - AES256 OFB (Cert. #2146)
   - SHA-384 (Cert. #1619) – used for digital signature verification during firmware integrity test and firmware load test. Used for password hashing for internal password storage.
   - HMAC SHA-384 (Cert. #1313)
   - SP800-56A KAS (Cert. #28) – (key agreement; key establishment methodology provides 192 bits of encryption strength)
   - ECDSA-384 (Cert. #263) – used for digital signature verification during firmware integrity test and firmware load test, and for key generation and signature generation.

The module supports the following non-Approved algorithms:
   - AES256 GCM (AES Cert. #2146; non-compliant)

The module supports the following allowed algorithms:
   - AES (Cert. #1876, key wrapping; key establishment methodology provides 256 bits of encryption strength) – used for key encryption
• AES MAC (Cert. #1876) – Used to provide authentication within APCO OTAR. AES MAC as used within APCO OTAR has been vendor affirmed and is approved when used for Project 25 APCO OTAR.

The following non-Approved algorithms and protocols are allowed within the Approved mode of operation:
  • Non-deterministic Hardware Random Number Generator – used for IV and key generation
3.2. Non Approved Mode of Operation

A non-FIPS Approved mode of operation is transitioned to when any of the following is true:

1. Clear Key Import is enabled.
2. Clear Key Export is enabled.
3. KLK generation is enabled.
4. Red Keyloading is enabled.
5. Encrypt or Decrypt service using AES-GCM mode is initiated.
4. Crypto Officer and User Guidance

4.1. Administration of the µMACE in a secure manner (CO)

The µMACE requires no special administration for secure use after it is set up for use in a FIPS Approved manner. To do this, configure the module as described in Section 3 of this document.

Note that all keys will be zeroized after the Program Update service has completed.

4.2. Assumptions regarding User Behavior (CO)

The µMACE has been designed in such a way that no special assumptions regarding User Behavior have been made that are relevant to the secure operation of the unit.

4.3. Approved Security Functions, Ports, and Interfaces available to Users

µMACE services available to the User role are listed in section 8.2.

No Physical Ports or Logical Interfaces are directly available to the µMACE User, only indirectly through the host product in which the µMACE is installed.

4.4. User Responsibilities necessary for Secure Operation

To ensure the secure operation of the µMACE the operator should periodically check the module for evidence of tamper. It is recommended that the µMACE be checked for evidence of tamper every 6 months.
5. Security Rules

The µMACE enforces the following security rules.

5.1. FIPS 140-2 Imposed Security Rules

1. The µMACE inhibits all data output via the data output interface whenever an error state exists and during self-tests.
2. The µMACE logically disconnects the output data path from the circuitry and processes when performing key generation or key zeroization.
3. Authentication data (e.g. passwords) are entered in encrypted form. Authentication data is not output during entry.
4. Secret cryptographic keys are entered in encrypted form.
5. The µMACE does not support manual key entry.
6. The µMACE enforces Identity-Based authentication.
7. The µMACE supports a User role, a Crypto-Officer role, and a KVL role. The module will verify the authorization of the operator to assume each role.
8. The µMACE re-authenticates an operator when it is powered-up after being powered-off.
9. The µMACE implements all firmware using a high-level language, except the limited use of low-level languages to enhance performance.
10. The µMACE protects secret keys and private keys from unauthorized disclosure, modification, and substitution.
11. The µMACE provides a means to ensure that a key entered into or stored within the module is associated with the correct entities to which the key is assigned. Each key in the µMACE is entered encrypted and stored with the following information:
   - Key Identifier – 16 bit identifier
   - Algorithm Identifier – 8 bit identifier
   - Key Type – Traffic Encryption Key or Key Encryption Key
   - Physical ID – Identifier indicating storage locations.
   Along with the encrypted key data, this information is stored in a key record that includes a CRC over all fields to protect against data corruption.
12. The µMACE denies access to plaintext secret and private keys contained within the module.
13. The Program Update service can be used to zeroize all plaintext cryptographic keys and other unprotected critical security parameters within the module.
15. The µMACE performs the following self-tests. Powering the module off then on will initiate the power up self-tests.
   - Power up and on-demand tests
     - Cryptographic algorithm test: A cryptographic algorithm test using a known answer is conducted for all cryptographic functions (e.g., encryption, decryption, authentication, random number generation, and hashing,) for each Approved algorithm listed below. The test passes if the final data matches the known data, otherwise it fails.
       - AES-256 (8-bit CFB, ECB, CBC, OFB, and CTR modes) encrypt / decrypt
- SHA-384
- HMAC SHA-384
- SP800-56A KAS (ECDH and ECMQV)
- Non-deterministic Hardware Random Number Generator entropy test
- ECDSA-384 (key generation)

Firmware integrity test: A digital signature is generated over the code when it is built using SHA-384 and ECDSA-384 and is stored with the code upon download into the module. When the module is powered up the digital signature is verified. If the digital signature matches, then the test passes, otherwise it fails.

Critical functions test: the module performs a read/write test of the internal RAM at each power up.

Conditional tests
- Firmware load test: A digital signature is generated over the code when it is built using SHA-384 and ECDSA-384. Upon download into the module, the digital signature is verified. If the digital signature matches, then the test passes, otherwise it fails.

Continuous Random Number Generator test: The continuous random number generator test is performed on all RNGs supported by the module (NDRNG). For each RNG, an initial value is generated and stored upon power up. This value is not used for anything other than to initialize comparison data. A successive call to any one of the RNGs generates a new set of data, which is compared to the comparison data. If a match is detected, this test fails; otherwise the new data is stored as the comparison data and returned to the caller.

Pair-wise consistency test (for public and private keys used to perform the calculation and verification of digital signatures): The ECDSA Public and Private Generated Signature Key pair is tested by the calculation and verification of a digital signature. If the digital signature cannot be verified, the test fails.

16. The µMACE toggles the Self-test Indicator interface within 2 seconds of power-up to indicate the Firmware Integrity Test, Firmware Load Test, Cryptographic Algorithm Test, and Critical Functions Test have completed successfully. The µMACE enters the Critical Error state and does not toggle the Self-test Indicator interface if the Firmware Integrity Test, Firmware Load Test, Cryptographic Algorithm Test, or Critical Functions Test fails. The Critical Error state may be exited by powering the module off then on.

17. The µMACE enters the Critical Error state and outputs a message over the SDIO interface to indicate the Continuous Random Number Generator Test and Pair-wise Consistency tests have failed. The Critical Error state may be exited by powering the module off then on.

18. The µMACE does not perform any cryptographic functions while in an error state.
6. Identification and Authentication Policy

The µMACE supports a User role, a Crypto-Officer role, and a KVL role.

The Crypto-Officer and User roles are authenticated with passwords. The Crypto-Officer and User passwords are initialized to a default value during manufacturing and are sent in encrypted form to the module for authentication. After authenticating, the Crypto-Officer and User passwords may be changed at any time.

The KVL role is authenticated by the KVL-BKK for Configure Module via KVL Interface, Zeroize Keys via KVL Interface, and Store & Forward services.

<table>

<td>attempts that can be performed over the KVL interface with the KVL-BKK in one minute is 745. Therefore the probability of a successful random attempt during a one-minute period is 745 in $2^{256}$ or 1 in $1.55425 	imes 10^{74}$.</td>
<td></td>
</tr>
</tbody>
</table>
7. **Physical Security Policy**

The µMACE is a production grade, single-chip cryptographic module as defined by FIPS 140-2 and is designed to meet Level 3 Physical Security.

The µMACE is covered with a hard opaque metallic coating that provides evidence of attempts to tamper with the module. Tampering with the module will cause it to enter a lock-up state in which no crypto services will be available.

No maintenance access interface is available.
8. Access Control Policy

8.1. µMACE Supported Roles

The µMACE supports three (3) roles. These roles are defined to be the:

- User Role
- Crypto-Officer Role
- KVL Role

8.2. µMACE Services Available to the User Role.

- Validate User Password: Validate the current User password used to identify and authenticate the User role via the SDIO interface. Successful authentication will allow access to crypto services allowed for the User. Available in both FIPS and non-FIPS mode.
- Change User Password: Modify the current password used to identify and authenticate the User Role via the SDIO interface. Available in both FIPS and non-FIPS mode.
- Algorithm List Query: Provides a list of algorithms over the SDIO interface. Available in both FIPS and non-FIPS mode.
- Logout User Role: Logs out the User. Available in both FIPS and non-FIPS mode.
- Export Key Variable: Transfer encrypted key variables (KEKs, TEKs) out of the module over the SDIO interface. Available in both FIPS and non-FIPS mode.
- Import Key Variable: Receive encrypted key variables (KEKs, TEKs, and ECMQV Private Static Key) over the SDIO interface. Available in both FIPS and non-FIPS mode.
- Generate Key Variable: Auto-generate KEKs, TEKs, ECDH Public and Private Values, Public and Private Generated Signature Keys, ECMQV Public Static Key, ECMQV Public and Private Generated Ephemeral Keys, ECDH Shared Secret, and the KPK within the module. Available in both FIPS and non-FIPS mode.
- Delete Key Variable: Delete KEKs, TEKs, ECDH Public and Private Values, ECDH Public and Private Generated Signature Keys, ECMQV Public and Private Static Keys, ECMQV Public and Private Generated Ephemeral Keys, and ECDH Shared Secret. Available in both FIPS and non-FIPS mode.
- Edit Key Variable: Edit KEKs and TEKs managed by the module. Available in both FIPS and non-FIPS mode.
- Key Check: Validate the correctness of a Key based on algorithm properties. Available in both FIPS and non-FIPS mode.
- Encrypt: Encrypt plaintext data to be transferred over the SDIO interface. Available in both FIPS and non-FIPS mode.
- Decrypt: Decrypt ciphertext data received over the SDIO interface. Available in both FIPS and non-FIPS mode.
- Transfer Key Variable: Internally transfer key variables (KEKs, TEKs) between volatile and non-volatile memory. Available in both FIPS and non-FIPS mode.
- Generate Signature: Generate a Signature and output result over SDIO interface. Available in both FIPS and non-FIPS mode.
- Generate Hash: Generate a hash and output result over SDIO interface. Available in both FIPS and non-FIPS mode.
- Generate MAC: This service generates a Message Authentication Code of a block of data to provide data integrity using a shared symmetric key.
- Perform Key Agreement Process: Perform a key agreement process to create a key in volatile memory. Available in both FIPS and non-FIPS mode.
- Generate Random Number: Generate random data using the Non-deterministic Hardware Random Number Generator and output result over SDIO interface. Available in both FIPS and non-FIPS mode.
- Key Query: Retrieve the metadata for a given key present in the module. Available in both FIPS and non-FIPS mode.
- OTAR: Modify and query the KEKs and TEKs stored internally via the SDIO interface.

8.3. µMACE Services Available to the Crypto-Officer Role.
- Program Update: Update the module firmware via the SDIO interface. All keys (stored in RAM and non-volatile memory) and CSPs are zeroized during a Program Update. Available in both FIPS and non-FIPS mode.
- Validate Crypto-Officer password: Validate the current Crypto-Officer password used to identify and authenticate the Crypto-Officer role via the SDIO interface. Successful authentication will allow access to services allowed for the Crypto Officer. Available in both FIPS and non-FIPS mode.
- Change Crypto-Officer password: Modify the current password used to identify and authenticate the Crypto-Officer Role via SDIO interface. Available in both FIPS and non-FIPS mode.
- Extract Action Log: Exports a history of actions over the SDIO interface. Available in both FIPS and non-FIPS mode.
- Logout Crypto-Officer Role: Logs out the Crypto-Officer. Available in both FIPS and non-FIPS mode.
- Configure Module via SDIO interface: Perform configuration of the module (e.g. time configuration, enable/disable clear key import, enable/disable red keyfill, etc.) via the SDIO interface. Available in both FIPS and non-FIPS mode.

8.4. µMACE Services Available to the KVL Role.
- Store & Forward: Modify and query the KEKs and TEKs stored internally via the KVL interface.
- Configure Module via KVL interface: Perform configuration of the module (e.g. OTAR configuration) via the KVL interface.
- Zeroize Keys via KVL interface: Zeroize KEKs and TEKs via the KVL interface.

8.5. µMACE Services Available Without a Role.
- Perform Self-Tests: Performs module self-tests comprised of cryptographic algorithms test and firmware test. Initiated by a transition from power off state to power on state. Available in both FIPS and non-FIPS mode.
- Version Query: Provides module firmware version number over the SDIO interface. Available in both FIPS and non-FIPS mode.
### 8.6. Critical Security Parameters (CSPs) and Public Keys

<table>
<thead>
<tr>

   Entry - on Program Update service request  
   Output - n/a  
   Storage - in plaintext in non volatile memory  
   Zeroization - on Program Update service request  
   Generation - n/a |
| **Traffic Encryption Keys (TEKs)** | 256-bit AES and HMAC SHA-384 Keys used for enabling secure communication with target devices. TEKs are entered in encrypted form via the SDIO or KVL interface (AES Key Wrapping), and internally derived through key agreement (generated internally - n/a on entry encryption). TEKs entered through the SDIO interface are encrypted with the BKK. TEKs entered through the KVL interface are encrypted with the KVL-BKK or KEKS. The TEKS are stored encrypted on the KPK (AES256-CFB8) in non volatile memory. TEKs are stored in plaintext in RAM only as long as needed. TEKs are output from the module on the SDIO interface encrypted using KEKs (AES Key Wrapping).  
   Entry – input encrypted with AES Key Wrap over the SDIO Interface or KVL interface  
   Output – output encrypted with AES Key Wrap over the SDIO Interface  
   Storage – stored encrypted on KPK with AES256-CFB8 in non volatile memory  
   Zeroization - on Delete Key Variable and Program Update service requests  
   Generation – internally derived through key agreement |
| **Key Encryption Keys (KEKs)** | 256-bit AES Keys used for enabling secure communication with target devices. KEKs are entered in encrypted form via the SDIO or KVL interface (AES Key Wrapping). KEKs entered through the KVL interface are encrypted with the KVL-BKK or other KEKS. KEKs entered through the SDIO interface are encrypted with other KEKS. The KEKS are stored encrypted on the KPK (AES256-CFB8) in non volatile memory. KEKS are stored in plaintext in RAM only as long as needed. KEKS are not output from the module.  
   Entry – input encrypted with AES Key Wrap over the SDIO or KVL Interface  
   Output - n/a  
   Storage – stored encrypted on KPK with AES256-CFB8 in non volatile memory |
