Overview

This document is a FIPS 140-2 Security Policy for Fortinet Incorporated’s FortiAnalyzer firmware for the FortiAnalyzer line of security appliances. This policy describes how the FortiAnalyzer firmware (hereafter referred to as the ‘module’) meets the FIPS 140-2 security requirements and how to operate the module in a FIPS compliant manner. This policy was created as part of the FIPS 140-2 Level 1 validation of the module.

This document contains the following sections:

- Introduction
- Security Level Summary
- Module Description
- Mitigation of Other Attacks
- FIPS 140-2 Compliant Operation
- Self-Tests

References

This policy deals specifically with operation and implementation of the module in the technical terms of the FIPS 140-2 standard and the associated validation program. Other FortiAnalyzer product manuals, guides and technical notes can be found at the Fortinet technical documentation website at http://docs.forticare.com.

Additional information on the entire FortiAnalyzer product line can be obtained from the following sources:

- Find on-line product support for registered products in the technical support section of the Fortinet corporate website at http://www.fortinet.com/support.
- Find contact information for technical or sales related questions in the contacts section of the Fortinet corporate website at http://www.fortinet.com/contact.
- Find security information and bulletins in the FortiGuard Center of the Fortinet corporate website at http://www.fortinet.com/FortiGuardCenter.

Introduction

The FortiAnalyzer family of logging, analyzing, and reporting appliances securely aggregate log data from Fortinet devices and other syslog-compatible devices. Using a comprehensive suite of customizable reports, users can filter and review records, including traffic, event, virus, attack, Web content, and email data.

A typical deployment architecture for a FortiAnalyzer appliance is shown in Figure 1.
Figure 1: A typical FortiAnalyzer deployment architecture

Security Level Summary

The module meets the overall requirements for a FIPS 140-2 Level 1 certification.

Module Description

The module is a firmware operating system that runs exclusively on Fortinet’s FortiAnalyzer product family. FortiAnalyzer units are PC-based, purpose built appliances. The FortiAnalyzer appliances are multiple chip, standalone cryptographic modules consisting of production grade components contained in a physically protected enclosure.

Figure 2: FortiAnalyzer Cryptographic Boundary

![FortiAnalyzer Hardware](image)

For the purposes of FIPS 140-2 conformance testing, the module was tested on the following FortiAnalyzer appliance:

- FortiAnalyzer-4000B

The module can also be executed on any of the following FortiAnalyzer appliances and remain FIPS compliant:

- FortiAnalyzer-100B
- FortiAnalyzer-100C
- FortiAnalyzer-400B
- FortiAnalyzer-800
- FortiAnalyzer-800B
- FortiAnalyzer-1000B
- FortiAnalyzer-1000C
- FortiAnalyzer-2000
- FortiAnalyzer-2000A
- FortiAnalyzer-2000B
- FortiAnalyzer-4000
- FortiAnalyzer-4000A

The validated firmware version is FortiAnalyzer 4.0, build3059, 130918.

Note that no claim can be made as to the correct operation of the module or the security strengths of the generated keys when ported to an operational environment which is not listed on the validation certificate.
Module Interfaces

The module's physical and logical interfaces are described in Table 2.

Table 2: FortiAnalyzer Crypto Module physical ports and logical interfaces

</table>

Web-Based Manager

The FortiAnalyzer web-based manager provides GUI based access to the module and is the primary tool for configuring the module. The manager requires a web browser on the management computer and an Ethernet connection between the FortiAnalyzer unit and the management computer.

A web-browser that supports Transport Layer Security (TLS) 1.0 is required for remote access to the web-based manager when the module is operating in FIPS mode. HTTP access to the web-based manager is not allowed in FIPS mode and is disabled.

The web browser is not part of the validated module boundary.
Command Line Interface

The FortiAnalyzer Command Line Interface (CLI) is a full-featured, text based management tool for the module. The CLI provides access to all of the possible services and configuration options in the module. The CLI uses a console connection or a network (Ethernet) connection between the FortiAnalyzer unit and the management computer. The console connection is a direct serial connection. Terminal emulation software is required on the management computer using either method. For network access, a Telnet or SSH client that supports the SSH v2.0 protocol is required (SSH v1.0 is not supported in FIPS mode).

The Telnet or SSH client is not part of the validated module boundaries.

Roles, Services and Authentication

Roles

When configured in FIPS mode, the module provides a Crypto Officer role and a Network User role.

The Crypto Officer role is initially assigned to the default ‘admin’ operator account. The Crypto Officer role has read-write access to the module’s administrative services. Crypto Officer access to the services can be customized using access profiles. A Crypto Officer with sufficient permissions can create or modify access profiles to limit access to the administrative services. When operator accounts are created, the Crypto Officer specifies an access profile for that operator.
The module provides a **Network User** role for remote IT entities. Network users can make use of the encrypt/decrypt services for the purpose of transferring log/content data to the module, but cannot access the module for administrative purposes.

The module does not provide a Maintenance role.

**FIPS Approved Services**

The following tables detail the types of FIPS approved services available to each role, the types of access for each role and the CSPs they affect.

The role names are abbreviated as follows:

- **Crypto Officer** (CO)
- **Network User** (NU)

The access types are abbreviated as follows:

- **Read Access** (R)
- **Write Access** (W)
- **Execute Access** (E)

</tbody>
</table>
Authentication

The modules implement identity based authentication. Operators must authenticate with a user-id and password combination to access the modules remotely or locally via the console. Remote operator authentication is done over HTTPS (TLS) or SSH. The password entry feedback mechanism does not provide information that could be used to guess or determine the authentication data.

Note that operator authentication over HTTPS/SSH and Network User authentication over HTTPS are subject to a limit of 3 failed authentication attempts in 1 minute. Operator authentication using the console is not subject to a failed authentication limit, but the number of authentication attempts per minute is limited by the bandwidth available over the serial connection.

The minimum password length is 8 characters when in FIPS mode (maximum password length is 32 characters). The password may contain any combination of upper- and lowercase letters, numbers, and printable symbols; allowing for 94 possible characters. The odds of guessing a password are 1 in 94^8 which is significantly lower than one in a million. Recommended procedures to increase the password strength are explained in “FIPS 140-2 Compliant Operation” on page 12.

Physical Security

The physical security for the module is provided by the FortiAnalyzer hardware which uses production grade components and an opaque enclosure.

Operational Environment

The module constitutes the entire firmware-based operating system for a FortiAnalyzer appliance and can only be installed, and run on, a FortiAnalyzer appliance. The module provides a proprietary and non-modifiable operating system and does not provide a programming environment.

For the purposes of FIPS 140-2 conformance testing, the module was tested on the following FortiMail appliances:

- FortiAnalyzer-4000B

Note that no claim can be made as to the correct operation of the module or the security strengths of the generated keys when ported to an operational environment which is not listed on the validation certificate.
Cryptographic Key Management

Random Number Generation

The modules use a firmware based, deterministic random number generator that conforms to ANSI X9.31 Appendix A.2.4.

The ANSI X9.31 RNG is seeded using a 128-bit AES seed key generated external to the module (estimated entropy 128 bits) and 256 bits of seed (estimated entropy 60 bits) gathered from a random pool filled with 64 bytes of system data and internal resources such as time, memory addresses, kernel ticks, and module identifiers. As the module's ANSI X9.31 RNG implementation only generates random values of size 128 bits, it would take multiple calls to form a 256-bit key. Each time a key is generated with a bit length of more than 128 bits, the key is refreshed with an additional 12 bits of entropy. The total estimated strength for the two calls required to form a 256 bit key would be at theoretical best 200 bits.

Key Zeroization

The zeroization process must performed under the direct control of the operator. The operator must be present to observe that the zeroization method has completed successfully.

All keys except the following are zeroized by executing a factory reset:

• ANSI X9.31 RNG AES Key
• Firmware Update Key
• Firmware Integrity Key
• Configuration Integrity Key
• Configuration Backup Key
• SSH Server/Host Key
• HTTPS/TLS Server/Host Key

All keys and CSPs are zeroized by formatting the modules’ flash memory storage. To format the flash memory, connect a computer to the modules' console port and reboot the module. Access the configuration menu by pressing any key when prompted (see example below). Select “F” to format the flash memory (boot device).

Press any key to display configuration menu...

[G]: Get firmware image from TFTP server.
[F]: Format boot device.
[B]: Boot with backup firmware and set as default.
[I]: Configuration and information.
[Q]: Quit menu and continue to boot with default firmware.
[H]: Display this list of options.

Enter G,F,B,I,Q,or H:
Algorithms

</table>
Alternating Bypass Feature

The primary function of the module is as a log and content aggregation device. Remote devices send log/content data to the FortiAnalyzer unit. Encrypt/decrypt operations are performed on incoming/outgoing traffic based on the configuration. Remote devices can be configured to send log/content data over a plain-text connection, an encrypted IPSec tunnel or an SSL encrypted connection using TLS 1.0.

A remote device configured to send log/content data using an IPSec tunnel or SSL connection means that the module is operating in a non-bypass state for communications with the device. A remote device configured to send log/content data using a plain-text connection means that the module is operating in a bypass state for communications with the device.

Key Archiving

The module supports key archiving to a management computer or USB token as part of a module configuration file backup. Operator entered keys are archived as part of the module configuration file. The configuration file is stored in plain text, but keys in the configuration file are either AES encrypted using the Configuration Encryption Key or stored as a keyed hash using HMAC-SHA-1 using the Configuration Backup Key.

Mitigation of Other Attacks

The module does not mitigate against any other attacks.

FIPS 140-2 Compliant Operation

FIPS 140-2 compliant operation requires both that you use the module in its FIPS mode of operation and that you follow secure procedures for installation and operation of the FortiAnalyzer unit. You must ensure that:

- The FIPS mode of operation is enabled
- The FortiAnalyzer unit is installed in a secure physical location.
- Physical access to the FortiAnalyzer unit is restricted to authorized operators.
- Administrative passwords are at least 8 characters long.
- Administrative passwords are changed regularly.
- Administrator account passwords must have the following characteristics:
  - One (or more) of the characters must be capitalized
  - One (or more) of the characters must be numeric
  - One (or more) of the characters must be non alpha-numeric (e.g. punctuation mark)
- Administration of the module is permitted using only validated administrative methods. These are:
  - Console connection
  - Web-based manager via HTTPS (TLS v1.0)
  - Command line interface (CLI) access via SSH (v2.0)
- Only approved and allowed algorithms are used (see “Algorithms” on page 10).
Enabling FIPS mode

To enable the FIPS mode of operation, the operator must execute the following command from the Local Console:

```
config system fips
set status enable
```

The Operator is required to supply a password for the admin account which will be assigned to the Crypto Officer role.

The supplied password must be at least 8 characters long and correctly verified before the system will restart in FIPS mode.

Upon restart, the module will execute self-tests to ensure the correct initialization of the module’s cryptographic functions.

After restarting, the Crypto Officer can confirm that the module is running in FIPS mode by executing the following command from the CLI:

```
get system status
```

If the module is running in FIPS mode, the system status output will display the line:

```
FIPS mode: enabled
```

Note that enabling/disabling the FIPS mode of operation will automatically invoke the key zeroization service. The key zeroization is performed immediately after FIPS mode is enabled/disabled.

Self-Tests

The module executes the following self-tests during startup and initialization:

- Firmware integrity test using RSA signatures
- Configuration/VPN bypass test using HMAC SHA-1
- Triple-DES, CBC mode, encrypt known answer test
- Triple-DES, CBC mode, decrypt known answer test
- AES, CBC mode, encrypt known answer test
- AES, CBC mode, decrypt known answer test
- HMAC SHA-1 known answer test
- SHA-1 known answer test (test as part of HMAC SHA-1 known answer test)
- HMAC SHA-256 known answer test
- SHA-256 known answer test (test as part of HMAC SHA-256 known answer test)
- RSA signature generation known answer test
- RSA signature verification known answer test
- RNG known answer test

The results of the startup self-tests are displayed on the console during the startup process. The startup self-tests can also be initiated on demand using the CLI command `execute fips kat all` (to initiate all self-tests) or `execute fips kat <test>` (to initiate a specific self-test).

When the self-tests are run, each implementation of an algorithm is tested - e.g. when the AES self-test is run, all AES implementations are tested.

The module executes the following conditional tests when the related service is invoked:

- Continuous RNG test
Non-FIPS Approved Services

- Continuous NDRNG test
- RSA pairwise consistency test
- Configuration/VPN bypass test using HMAC SHA-256
- Firmware load test using RSA signatures

If any of the self-tests or conditional tests fail, the module enters a FIPS error mode. For example, if the AES self-test fails, the following would be displayed on the console:

Entering FIPS Error Mode because of the following issues:
1. SELF_TEST_AES_Failed

You must power cycle the unit to recover.

The system is going down NOW !!
Pausing log daemons...
Stopping RAID ...

The system is halted...

All data output and cryptographic services are inhibited in the error state.

Non-FIPS Approved Services

The module also provides the following non-FIPS approved service:
- Configuration backups using password protection

If the above service issued, the module is not considered to be operating in the FIPS approved mode of operation.
