1 Overview

This document defines the non-proprietary Security Policy for the Nutanix Cryptographic Module for OpenSSH Client, hereafter denoted the module. The module is a cryptographic software library, designated as multi-chip standalone embodiment in [140] terminology, used in Nutanix, Inc. (Nutanix) solutions to provide FIPS 140-2 Approved SSH client-side secure communication.

The module meets FIPS 140-2 overall Level 1 requirements, with security levels as follows:

Table 1: Security Level of Security Requirements

| Security Requirement | Security Level |
|---|----------------|
| Cryptographic Module Specification | 1 |
| Cryptographic Module Ports and Interfaces | 1 |
| Roles, Services, and Authentication | 1 |
| Finite State Model | 1 |
| Physical Security | N/A |
| Operational Environment | 1 |
| Cryptographic Key Management | 1 |
| EMI/EMC | 1 |
| Self-Tests | 1 |
| Design Assurance | 1 |
| Mitigation of Other Attacks | N/A |

In Table 1 above, [140] Section 4.5 *Physical Security* is not applicable, as permitted by [140IG] 1.16 *Software Module* and [140IG] G.3 *Partial Validations and Not Applicable Areas of FIPS 140-2*.

The module design corresponds to the module security rules. Security rules enforced by the module are described in the appropriate context of this document.

The module is bound to FIPS 140-2 Cert. #3460 - *Nutanix Cryptographic Module for OpenSSL*. This security policy represents the complete, composite functionality of this module: the SSHv2 service implemented using the cryptographic primitives of Cert. #3460. Unlike Cert. #3460, the module does not offer a set of cryptographic primitives, rather it provides only the SSHv2 subsystem. Specifically:

- The logical boundary of this module is shown below; the logical boundary of the bound (Cert. #3460) module is not within the boundary of this module.
- Table 4 lists all approved cryptographic algorithms used by this module, inclusive of those implemented in Cert. #3460.
- Table 5 lists the non-approved algorithms that are possible by configuring the SSH subsystem using non-approved SSH parameters.
- The CSPs and public keys listed in this security policy are those accessed by this module.
- The module provides the software integrity test described in Section 6.

The module operates within a general-purpose computer. Figure 1 depicts the module operational environment, with the logical boundary highlighted in red inclusive of all module entry points (API calls), conformant with [140IG] 14.3 *Logical Diagram for Software, Firmware and Hybrid Modules*.

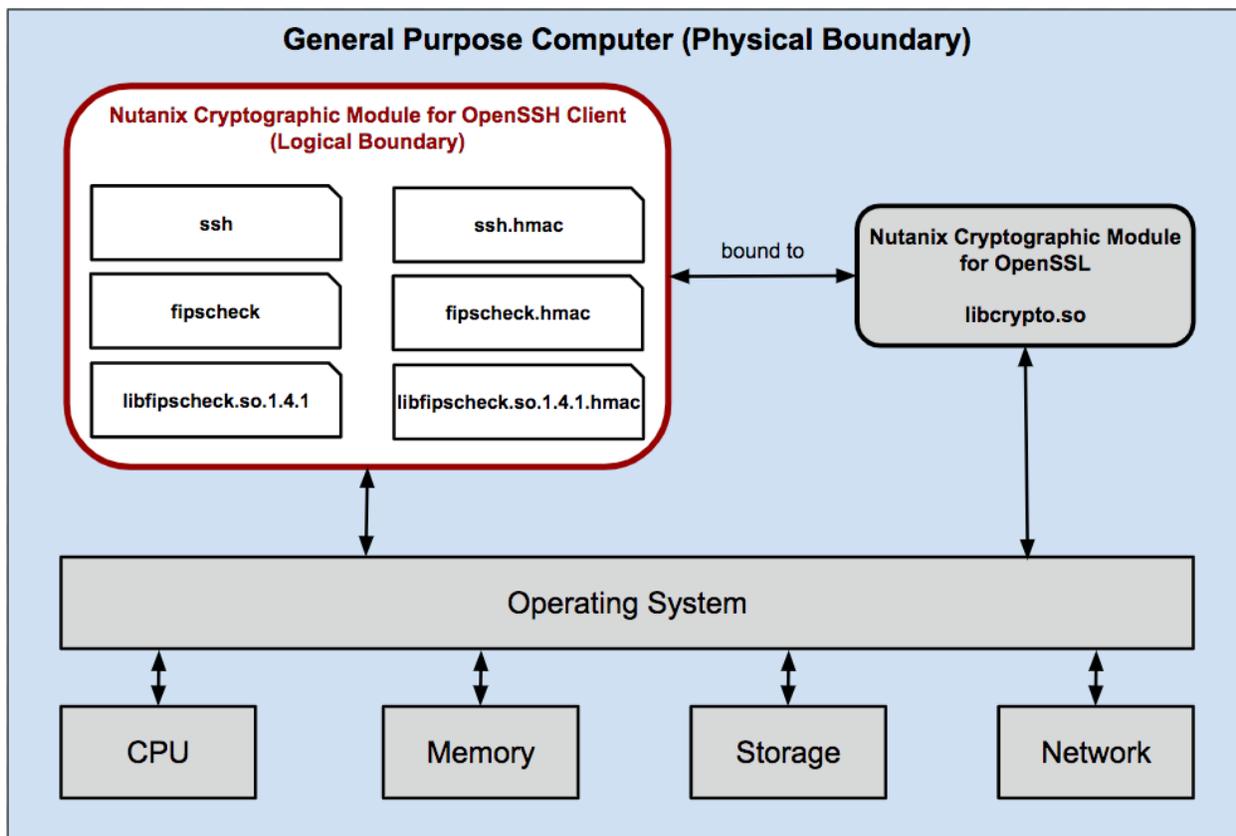

Figure 1: Module Physical and Logical Boundary

The module conforms to [140IG] 1.16 Software Module:

- The physical cryptographic boundary is the general-purpose computer which wholly contains the module and operating system.
- The logical cryptographic boundary is the set of shared library files and associated HMAC files:
 - ssh, ssh.hmac
 - fipscheck, fipscheck.hmac
 - libfipscheck.so.1.4.1, libfipscheck.so.1.4.1.hmac
- All components are defined in accordance with [140DTR] AS01.08; no components are excluded from [140] requirements.
- The power-up approved integrity test is performed over all components within the logical boundary.
- Updates to the module are provided as a complete replacement in accordance with [140IG] 9.7 Software/Firmware Load Test.
- Table 2 defines the module’s [140] logical interfaces.

Table 2: Ports and Interfaces

| Description | Logical Interface Type |
|---|---|
| Terminal I/O (command line in, display out) | Control input, status output |
| File I/O (Configuration, key and log files) | Control input, data input, status output |
| TLS module API (calls to libcrypto.so services) | Control input, data input, data output, Status output |
| Network traffic | Control input, data input, data output, Status output |

Software versions:

- OpenSSH client RPM package 7.4p1-16.el7
- fipscheck RPM package 1.4.1-6.el7

Operational testing was performed on the Operating Environments listed in Table 3.

Table 3: Tested Operating Environments

| Operating System | Processor | Platform |
|------------------|------------------------------------|--------------------|
| CentOS 7.5 | Intel Xeon Silver-4116 with PAA | Nutanix NX-3360-G6 |
| CentOS 7.5 | Intel Xeon Silver-4116 without PAA | Nutanix NX-3360-G6 |

The module conforms to [140IG] 6.1 *Single Operator Mode and Concurrent Operators*. The tested environments place user processes into segregated spaces. A process is logically removed from all other processes by the hardware and Operating System. Since the module exists inside the process space of the application this environment implicitly satisfies requirement for a single user mode.

2 Cryptographic Functionality

The module implements the FIPS Approved cryptographic functions listed in Table 4. [57P1] notation is used throughout this document to describe key sizes and security strength. Items in curly brackets { } are tested but not used by the module.

Table 4: Approved CAVP Validated Cryptographic Functions

| Cert | Algorithm | Mode | Description | Functions, Caveats |
|---|--------------------------|---|--|--|
| <i>Implemented by this module (Nutanix Cryptographic Module for OpenSSH Client)</i> | | | | |
| 1998 | CVL: SSH KDF [135] | SSHv2 key derivation | | Key derivation |
| <i>Implemented by Cert. #3460 (Nutanix Cryptographic Module for OpenSSL)</i> | | | | |
| 5562 , C661 | AES [197] | CBC [38A] | Key sizes: 128, 192, 256 | Encryption, Decryption |
| | | CCM [38C] | Key sizes: 128, 192, 256 | Authenticated Encryption, Authenticated Decryption |
| | | GCM [38D] | Key sizes: 128, {192}, 256 | Authenticated Encryption, Authenticated Decryption, Message Authentication |
| 1994 | CVL: KAS [56A] Primitive | FFC | FB $L \geq 2048$ $N = 224$ FC $L \geq 2048$ $N = 256^1$ | Key Agreement: All KAS Initiator and Responder functions except KDF |
| | | ECC | P-256, P-384, P-521 ² | |
| 2216 | DRBG [90A] | CTR_DRBG {Hash_DRBG} {HMAC_DRBG} | AES: {128, 192}, 256 (bits) {Other DRBG variants and strengths are tested on the bound module cert but are not used by this module} | Random bit generation |
| 1499 | ECDSA [186] | P-256, P-384, P-521 with SHA-2 {Other curves and SHA combinations are tested on the bound module cert but are not used by this module} | | Signature Generation, Signature Verification {Key generation and key verification are not used} |
| 3708 | HMAC [198] | SHA-1, SHA-256, SHA-384 {Other SHA sizes are tested on the bound module cert but are not used by this module} | | Generation, Verification, (Message Authentication) |
| N/A | NDRNG | Entropy sourced by the NDRNG is used to seed the SP800-90A default AES-256 CTR_DRBG | | Non-approved but allowed |
| 4465 | SHS [180] | SHA-1, SHA-224, SHA-256, SHA-384, SHA-512 | | Message Digest |

¹ Diffie-Hellman: key establishment methodology provides 112 bits of encryption strength

² EC Diffie-Hellman: key establishment methodology provides between 128 and 256 bits of encryption strength.

The module conforms to [140IG] D.11 *References to the Support of Industry Protocols* (Resolution scenario 2) by providing CAVP validated [56A] components along with the CAVP validated [135] Section 4.2 KDF for SSHv2. In accordance with [140IG] D.11, the remainder of the SSHv2 protocol has not been reviewed or tested by the CAVP and CMVP.

The module implements the non-Approved but allowed cryptographic functions listed in Table 5.

Table 5: Non-Approved but Allowed Cryptographic Functions

| Cryptographic Function | Description / Usage |
|------------------------|--|
| Diffie-Hellman | Key Agreement: FB $L \geq 2048$ $N = 224$; FC $L \geq 2048$ $N = 256$ |
| EC Diffie-Hellman | Key Agreement: P-256, P-384, P-521 |

3 Modes of Operation, Security Rules and Guidance

The module supports a FIPS Approved mode of operation and a non-FIPS Approved mode of operation, and conforms to [140IG] 1.2 *FIPS Approved Mode of Operation* and 1.19 *non-Approved Mode of Operation*.

The conditions for using module cryptographic primitives in the [140] Approved mode of operation are:

1. Only the ssh parameters listed in Table 6 are to be used. Key pairs generated external to the module for use with key exchange and client authentication must comply to the Table 6 parameters.
2. SSH protocol version 1 is not usable in the approved mode; SSH protocol version 2 must be enabled.
3. GSS API authentication is not allowed.
4. If module power is lost and restored, a new key for use with AES GCM cipher is established.
5. Data output is inhibited during self-tests, zeroization, and error states.
6. Status information does not contain CSPs or sensitive data that if misused could lead to module compromise.

Table 6: SSH Parameters Used in the Approved Mode of Operation

| Key exchange | Client authentication | Cipher | MAC |
|-------------------------------|-----------------------|-------------------------|--------------------------------|
| diffie-hellman-group14-sha1 | ecdsa-sha2-nistp256 | aes256-cbc | hmac-sha1 |
| diffie-hellman-group14-sha256 | ecdsa-sha2-nistp384 | aes192-cbc | hmac-sha2-256 |
| ecdh-sha2-nistp256 | ecdsa-sha2-nistp521 | aes128-cbc | aes-128-gcm ³ |
| ecdh-sha2-nistp384 | | aes128-ctr | aes-256-gcm ³ |
| ecdh-sha2-nistp521 | | aes192-ctr | hmac-sha2-256-etm ⁴ |
| | | aes256-ctr | hmac-sha1-etm |
| | | aes128-gcm ³ | |
| | | aes256-gcm ³ | |

The SSH parameters are set as described in the corresponding Nutanix User Guide. To confirm the settings for the above SSH parameters, query the running instance of ssh as follows:

- Key exchange algorithms: ssh -Q kex
- Host key algorithms: ssh -Q key
- Cipher algorithms: ssh -Q cipher
- MAC (message integrity) algorithms: ssh -Q mac

³ For GCM integrity, GMAC is not explicitly named in configuration or negotiated; integrity is accomplished as a facet of the GCM authenticated cipher functionality.

⁴ *etm* refers to “encrypt then MAC” - the HMAC is performed on the ciphertext message content

Table 7 lists ciphersuites available in the non-approved mode of operation.

Table 7: SSH Parameters Used in the Non-Approved Mode of Operation

| Key exchange | Client authentication | Cipher | Digest |
|--|-----------------------|--------------|------------------|
| diffie-hellman-group1-sha1 | sha-rsa | rijndael-cbc | All are approved |
| diffie-hellman-group-exchange-sha1 | | 3des-cbc | |
| diffie-hellman-group-exchange-sha256 | | | |
| curve25519-sha256 | | | |
| diffie-hellman-group16-sha512 ⁵ | | | |
| diffie-hellman-group18-sha512 ⁶ | | | |

4 Critical Security Parameters and Public Keys

All CSPs and public keys used by the module are described in this section. The module does not implement random number generation or key pair generation, instead using those provided by the bound OpenSSL libcrypto.so services. The module and an external ssh daemon perform the SSH protocol, the module calls the libcrypto shared secret generation primitive, then calls its SSHv2 KDF to derive the session keys from the shared secret. The session keys are provided to libcrypto.so for message cipher (encrypt/decrypt) and integrity functions. Table 8 summarizes the CSPs and public keys implemented by the module.

Table 8: Critical Security Parameters (CSPs) and Public Keys

| CSP | Description/Usage | Key generation | Key storage | Key entry/output | Key Zeroization |
|------------------------|--|---|---------------|--|-----------------|
| Shared secret | Secure communications shared secret, used to derive session keys | Obtained from call to libcrypto.so | Module memory | Entry: N/A Output: N/A | Zeroized by ssh |
| Session keys | Secure communications session keys used for message ciphering and integrity | Derived by the module using the SSHv2 KDF | Module memory | Entry: N/A Output: N/A | Zeroized by ssh |
| Client key pairs | ECC or FFC key pair used for key exchange; ECC key pair used key for client authentication | N/A | Module memory | Entry: N/A Output: public key to peer | Module removal |
| Server public key | ECC or FFC key used for key exchange | N/A | Module memory | Entry: From peer* Output: N/A | N/A |
| Software integrity key | Verification of software file integrity | N/A | Module binary | Entry: N/A Output: N/A | Module removal |

Session message cipher key: AES-128, AES-192, or AES-256 key.

Session message integrity key: HMAC-SHA-1, HMAC-SHA-256, HMAC-SHA-512, or AES-128 or AES-256 (GCM). HMAC message authentication key lengths are equal to the digest size.

Client key pairs and server public key: ECC (P-256, P-384, P-521).

Software integrity key: HMAC-SHA-256 (128-bit key).

*Key entry/output is interpreted based on [140IG] 7.7; no CSPs cross the physical boundary, rather, local private and public keys are obtained from files within the boundary; and the shared secret is obtained by API interaction with the libcrypto.so within the boundary. Public keys are exchanged over the network port in the SSH handshake.

⁵ Uses a 4096-bit modulus: sizes over 2048 bits are allowed but are not defined by [56A]

⁶ Uses a 8192-bit modulus: sizes over 2048 bits are allowed but are not defined by [56A]

5 Roles and Services

The module supports two distinct operator roles, User and Cryptographic Officer (CO), and does not support multiple concurrent operators, a maintenance role or bypass capability. The CO and the User roles are implicitly identified by the service requested.

All services implemented by the module are listed in Table 9. This table describes module service access to CSPs and public keys, where I indicates *input*, O indicates *output*, G indicates *generate* (use of the SSHv2 KDF), X indicates *execute* (use of the CSP or public key by a function), and Z indicates *zeroize*. Note that I and O are relative to the logical interfaces; the module does not output any CSP over the physical boundary, and the guidance of [140IG] 7.7 applies where entry and output are considered N/A between software components internal to the general-purpose computer. The server public is marked I as it crosses the physical boundary via the network port.

Table 9: Authorized Services Available in FIPS Mode

| Service | Description | Role | CSP and public key access |
|-----------------------|---|------|---|
| Install | Install the module | CO | N/A |
| Configure | Configure the module | CO | N/A |
| Launch (Self-Test) | Launch the ssh application (includes self-test) | User | Software integrity key: X |
| Secure communications | Establish and use ssh secure communications channel | User | Client private key: X Client public key: O Server public key: I, X Shared secret: X, Z Session keys: G, X |
| Close | Close ssh secure communications channel | User | Session keys: Z |
| Show status | Show ssh status | User | N/A |
| Terminate (Zeroize) | Shut down the ssh application | User | Shared secret: Z Session keys: Z |

6 Self-test

The module performs the software integrity check using HMAC-SHA-256 on initialization of the ssh executable. The ssh application calls the fipscheck utility via the fipscheck.so library, which tests the fipscheck binary, the fipscheck shared library and the calling application binary (ssh). The fipscheck utility returns a non-zero error code on failure, with a corresponding error log message “Hmac mismatch on file <filename>”, where filename is the fipscheck binary, fipscheck.so or the ssh binary file name, inclusive of path.

All algorithms provided by the Nutanix Cryptographic Module for OpenSSH (the cryptographic primitives library this module is bound to) are self-tested when the library (libcrypto.so) is loaded.

The module returns an error code and enters the error state if any of the power-on self-tests fail.

The fipscheck utility exit value indicates the comparison result, either zero if the integrity tests succeed, or an error code if any of the integrity tests fail (resulting in termination of the ssh application).
