## Authority

61 This publication has been developed by NIST in accordance with its statutory responsibilities  
62 under the Federal Information Security Modernization Act (FISMA) of 2014, 44 U.S.C. § 3551 *et*  
63 *seq.*, Public Law (P.L.) 113-283. NIST is responsible for developing information security  
64 standards and guidelines, including minimum requirements for federal information systems, but  
65 such standards and guidelines shall not apply to national security systems without the express  
66 approval of appropriate federal officials exercising policy authority over such systems. This  
67 guideline is consistent with the requirements of the Office of Management and Budget (OMB)  
68 Circular A-130.

69 Nothing in this publication should be taken to contradict the standards and guidelines made  
70 mandatory and binding on federal agencies by the Secretary of Commerce under statutory  
71 authority. Nor should these guidelines be interpreted as altering or superseding the existing  
72 authorities of the Secretary of Commerce, Director of the OMB, or any other federal official. This  
73 publication may be used by nongovernmental organizations on a voluntary basis and is not subject  
74 to copyright in the United States. Attribution would, however, be appreciated by NIST.

75 National Institute of Standards and Technology Special Publication 800-191

79 Certain commercial entities, equipment, or materials may be identified in this document in order to describe an  
80 experimental procedure or concept adequately. Such identification is not intended to imply recommendation or  
81 endorsement by NIST, nor is it intended to imply that the entities, materials, or equipment are necessarily the best  
82 available for the purpose.

83 There may be references in this publication to other publications currently under development by NIST in accordance  
84 with its assigned statutory responsibilities. The information in this publication, including concepts and methodologies,  
85 may be used by federal agencies even before the completion of such companion publications. Thus, until each  
86 publication is completed, current requirements, guidelines, and procedures, where they exist, remain operative. For  
87 planning and transition purposes, federal agencies may wish to closely follow the development of these new  
88 publications by NIST.

89 Organizations are encouraged to review all draft publications during public comment periods and provide feedback  
90 to NIST. Many NIST cybersecurity publications, other than the ones noted above, are available at  
91 <http://csrc.nist.gov/publications>.

## Reports on Computer Systems Technology

101 The Information Technology Laboratory (ITL) at the National Institute of Standards and  
102 Technology (NIST) promotes the U.S. economy and public welfare by providing technical  
103 leadership for the nation’s measurement and standards infrastructure. ITL develops tests, test  
104 methods, reference data, proof of concept implementations, and technical analysis to advance the  
105 development and productive use of information technology. ITL’s responsibilities include the  
106 development of technical, physical, administrative, and management standards and guidelines for  
107 the cost-effective security and privacy of sensitive unclassified information in Federal computer  
108 systems. This Special Publication 800-series reports on ITL’s research, guidance, and outreach  
109 efforts in computer security and its collaborative activities with industry, government, and  
110 academic organizations.

111

### Abstract

112 Managing the data generated by Internet of Things (IoT) sensors is one of the biggest challenges  
113 faced when deploying an IoT system. Traditional cloud-based IoT systems are challenged by the  
114 large scale, heterogeneity, and high latency witnessed in some cloud ecosystems. One solution is  
115 to decentralize applications, management, and data analytics into the network itself using a  
116 distributed and federated compute model. This approach has become known as fog  
117 computing. This document presents a formal definition of fog and mist computing and how they  
118 relate to cloud-based computing models for IoT. This document further characterizes important  
119 properties and aspects of fog computing, including service models, deployment strategies, and  
120 provides a baseline of what fog computing is, and how it may be used.

121

## 160 **1 Introduction**

161 Ubiquitous deployment of smart, interconnected devices is estimated to reach 50 billion units by  
162 2020<sup>1</sup>. This exponential increase is fueled by the proliferation of mobile devices (e.g. mobile  
163 phones and tablets), smart sensors serving different vertical markets (e.g. smart power grids,  
164 autonomous transportation, industrial controls, smart cities, wearables, etc), wireless sensors and  
165 actuators networks. New concepts and technologies are needed to manage this growing fleet of  
166 Internet of Things (IoT) devices.

### 167 **1.1 Purpose and Scope**

168 The acute need of the multitude of smart, end-user IoT devices and near-user edge devices to carry  
169 out, with minimal latency, a substantial amount of data processing and to collaborate in a  
170 distributed way, triggered technology advancements towards adaptive, decentralized  
171 computational paradigms that complement the centralized cloud computing model serving IoT  
172 networks.

173 Researchers, computer scientists, system and network engineers developed innovative solutions to  
174 fill the technological gaps. These solutions provide faster approaches that gain better situational  
175 awareness in a far more timelier manner. Such solutions or computational paradigms are referred  
176 to as *fog computing*, *mist computing*, *cloudlets*, or *edge computing*. Since no clear distinction  
177 among these concepts existed at the time the document was created, the authors considered it  
178 imperative to provide a formal definition that best matches the experts' views.

179 This document provides a formal definition of *fog computing* and its subsidiary *mist computing*  
180 concept, and aims to place these concepts in relation to *cloud computing*, *cloudlets* and *edge*  
181 *computing*.

182 Additionally, the document introduces the notion of a *fog node* and the *nodes federation model*  
183 composed of both, distributed and centralized clusters of fog nodes operating in harmony. This  
184 model is introduced as a building-block architectural approach for constructing, enhancing or  
185 expanding the *fog* and *mist computing* layers.

186 Furthermore, the document characterizes important aspects of *fog computing* and is intended to  
187 serve as a means for broad comparisons of fog capabilities, service models and deployment  
188 strategies, and to provide a baseline for discussion of what *fog computing* is and the way it may be  
189 used.

190 The capabilities, service types and deployment models form a simple taxonomy that is not intended  
191 to prescribe or constrain any particular method of deployment, service delivery, or business  
192 operation.

194 **2 The NIST Definition of Fog Computing**

195 **2.1 Fog Computing Definition**

196 Fog computing is a horizontal, physical or virtual resource paradigm that resides between *smart*  
 197 end-devices and traditional cloud or data centers. This paradigm supports vertically-isolated,  
 198 latency-sensitive applications by providing ubiquitous, scalable, layered, federated, and distributed  
 199 computing, storage, and network connectivity.  
 200  
 201

202 **Figure 1 – Fog computing supporting a cloud-based ecosystem for smart end-devices.**  
 203  
 204

205 Figure 1 above depicts fog computing in the broader context of a cloud-based ecosystem serving  
 206 smart end-devices. It is important to note that, in authors' view, fog computing is not perceived as  
 207 a mandatory layer for such ecosystem.  
 208

209 **2.2 Fog Computing Characteristics**

210 **Contextual location awareness, and low latency.** The origins of the Fog can be traced to  
 211 early proposals supporting endpoints with rich services at the edge of the network, including  
 212 applications with low latency requirements (e.g. gaming, video streaming, and augmented

213 reality). Because Fog nodes tend to sit very close to the IoT endpoints, analysis and response  
214 to data generated by the endpoints is much quicker than from a centralized cloud.

215 **Geographical distribution.** In sharp contrast to the more centralized Cloud, the services and  
216 applications targeted by the Fog demand widely distributed deployments. For instance, the Fog  
217 will play an active role in delivering high quality streaming services to moving vehicles,  
218 through proxies and access points positioned along highways and tracks.

219 **Large-scale sensor networks** to monitor the environment, and the Smart Grid are other  
220 examples of inherently distributed systems, requiring distributed computing and storage  
221 resources.

222 **Very large number of nodes**, as a consequence of the wide geo-distribution, as evidenced in  
223 sensor networks in general, and the Smart Grid in particular.

224 **Support for mobility.** It is essential for many Fog applications to communicate directly with  
225 mobile devices, and therefore support mobility techniques, such as the LISP protocol, that  
226 decouple host identity from location identity, and require a distributed directory system.

227 **Real-time interactions.** Important Fog applications involve real-time interactions rather than  
228 batch processing.

229 **Predominance of wireless access.** Although Fog computing is used in wired environments,  
230 the large scale of wireless sensors in IoT demand distributed analytics and compute. For this  
231 reason, Fog is very well suited to wireless IoT access networks.

232 **Heterogeneity.** Fog nodes come in different form factors, and will be deployed in a wide  
233 variety of environments, and the devices they collect data from may also vary in form factor  
234 and network communication capability.

235 **Interoperability and federation.** Seamless support of certain services (real-time streaming  
236 services is a good example) requires the cooperation of different providers. Hence, Fog  
237 components must be able to interoperate, and services must be federated across domains.

238 **Support for real-time analytics and interplay with the Cloud.** The Fog is positioned to play  
239 a significant role in the ingestion and processing of the data close to the source as it is being  
240 produced. While Fog nodes provide localization, therefore enabling low latency and context  
241 awareness, the Cloud provides global centralization. Many applications require both Fog  
242 localization and Cloud globalization, particularly for analytics and Big Data. Fog is particularly  
243 well suited to real-time streaming analytics as opposed to historical, Big Data batch analytics  
244 that is normally carried out in a data center.

245

## 246 **2.3 Fog Node Definition**

247 Fog nodes are intermediary compute elements of the smart end-devices access network that are  
248 situated between the Cloud and the smart end-devices. Fog nodes may be either *physical* or *virtual*  
249 elements and are tightly coupled with the smart end-devices or access networks. Fog nodes  
250 typically provide some form of data management and communication service between the  
251 peripheral layer where smart end-devices reside and the Cloud. Fog nodes, especially virtual ones,

252 also referred as *cloudlets*, can be federated to provide horizontal expansion of the functionality  
253 over disperse geolocations.

## 254 **2.4 Fog Node Architectural Service Types**

255 Fog computing is an extension of the traditional cloud-based computing model where  
256 implementations of the architecture can reside in multiple layers of a network's topology. Similar  
257 to cloud, the following types of service models can be implemented:  
258

259 ***Software as a Service (SaaS)***. The capability provided to the fog service customer is to use the fog  
260 provider's applications running on a cluster of federated fog nodes managed by the provider. This  
261 type of service is similar to the cloud computing Software as a Service (SaaS) and implies that the  
262 end-device or smart thing access the fog node's applications through a thin client interface or a  
263 program interface. The end-user does not manage or control the underlying fog node's  
264 infrastructure including network, servers, operating systems, storage, or even individual  
265 application capabilities, with the possible exception of limited user-specific application  
266 configuration settings.

267 ***Platform as a Service (PaaS)***. The capability provided to the fog service customer is similar to the  
268 cloud computing Platform as a Service (PaaS) and allows deployment onto the platforms of  
269 federated fog nodes forming a cluster, of customer-created or acquired applications created using  
270 programming languages, libraries, services, and tools supported by the fog service provider. The  
271 fog service customer does not manage or control the underlying fog platform(s) and infrastructure  
272 including network, servers, operating systems, or storage, but has control over the deployed  
273 applications and possibly configuration settings for the application-hosting environment.

274 ***Infrastructure as a Service (IaaS)***. The capability provided to the fog service customer is to  
275 provision processing, storage, networks, and other fundamental computing resources leveraging  
276 the infrastructure of the fog nodes forming a federated cluster. Similar to cloud Infrastructure as a  
277 Service (IaaS) services, the customer is able to deploy and run arbitrary software, which can  
278 include operating systems and applications. The consumer does not manage or control the  
279 underlying infrastructure of the fog nodes cluster but has control over operating systems, storage,  
280 and deployed applications; and possibly limited control of select networking components (e.g.,  
281 host firewalls).

## 282 **2.5 Fog Node Deployment Models**

283 Since fog computing is identified and defined as an extension of the traditional cloud-based  
284 computing model, the following deployment models are also supported:

285 ***Private fog node***. A fog node that is provisioned for exclusive use by a single organization  
286 comprising multiple consumers (e.g., business units.) It may be owned, managed, and operated by  
287 the organization, a third party, or some combination of them, and it may exist on or off premises.

288 ***Community fog node***. A fog node that is provisioned for exclusive use by a specific community  
289 of consumers from organizations that have shared concerns (e.g., mission, security requirements,  
290 policy, and compliance considerations.) It may be owned, managed, and operated by one or more  
291 of the organizations in the community, a third party, or some combination of them, and it may  
292 exist on or off premises.

293 **Public fog node.** A fog node that is provisioned for open use by the general public. It may be  
294 owned, managed, and operated by a business, academic, or government organization, or some  
295 combination of them. It exists on the premises of the fog provider.

296 **Hybrid fog node.** A complex fog node that is a composition of two or more distinct fog nodes  
297 (private, community, or public) that remain unique entities, but are bound together by standardized  
298 or proprietary technology that enables data and application portability (e.g., fog bursting for load  
299 balancing between these fog nodes.)

300

### 301 **3 Mist Computing as Lightweight Fog Layer**

302 Fog computing solutions are adopted by many industries, and efforts to develop distributed  
303 applications and analytics tools exist and continue to develop. The need for geographically  
304 disbursed, low-latency computational resources triggered the technological evolution of fog  
305 computing promoting development of more specialized, dedicated nodes that exhibit low  
306 computational resources. These nodes referred to as mist nodes, are perceived as *lightweight* fog  
307 nodes. These mist nodes that form the mist computing layer are placed even closer to the peripheral  
308 devices and users than the more powerful fog nodes they collaborate with, often sharing same  
309 locality with the smart end-devices they service.

#### 310 **3.1 Mist Computing Definition**

311 Mist computing is a lightweight and rudimentary form of computing power that resides directly  
312 within the network fabric<sup>2</sup> at the edge of the network fabric, the fog layer closest to the smart end-  
313 devices, using microcomputers and microcontrollers to feed into fog computing nodes and  
314 potentially onward towards the cloud computing services.

315 Mist layer is not viewed as a mandatory layer of fog. When implemented, mist nodes can leverage  
316 the deployment models described in Section 2.5 and the service types described in Section 2.4.

317

---

<sup>2</sup> Network fabric is an industry term that describes a [network topology](#) in which components pass data to each other through interconnecting switches.

**Annex A—Fog Computing vs. Edge Computing**

319  
320 For the purpose of this document, the *Edge* is the network layer encompassing the smart end-  
321 devices and their users, to provide, for example, local computing capability on a sensor, metering  
322 or some other devices that are network-accessible. This peripheral layer is also often referred to as  
323 IoT network.

324 Fog computing also is often erroneously called edge computing, but there are key differences. Fog  
325 works with the cloud, whereas edge is defined by the exclusion of cloud and fog. Fog is  
326 hierarchical, where edge tends to be limited to a small number of peripheral layers. Moreover, in  
327 addition to computation, fog also addresses networking, storage, control and data-processing  
328 acceleration.

329

**330 Acronyms**

331 Selected acronyms and abbreviations used in this paper are defined below.

IaaS                      Infrastructure as a Service

IoT                        Internet of Things

PaaS                      Platform as a Service

SaaS                      Software as a Service

332
