

**This (First) DRAFT of Special Publication 800-177 document has been superseded by the following draft publication:**

**The first draft has been attached for HISTORICAL PURPOSE – PLEASE refer to the Second Draft (see details below):**

Publication Number:     **Second Draft Special Publication 800-177**

Title:                     **Trustworthy Email**

Publication Date:       **March 2016**

- Second Draft Publication:  
<http://csrc.nist.gov/publications/PubsDrafts.html#800-177>
- Information on other publications:  
<http://csrc.nist.gov/publications/>

The following information was posted with the attached DRAFT document:

NIST requests comments on the second draft of Special Publication (SP) 800-177, *Trustworthy Email*. This draft is a complimentary guide to NIST SP 800-45 Guidelines on Electronic Mail Security and covers protocol security technologies to secure email transactions. This draft guide includes recommendations for the deployment of domain-based authentication protocols for email as well as end-to-end cryptographic protection for email contents. Technologies recommended in support of core Simple Mail Transfer Protocol (SMTP) and the Domain Name System (DNS) include mechanisms for authenticating a sending domain (Sender Policy Framework (SPF), Domain Keys Identified Mail (DKIM) and Domain based Message Authentication, Reporting and Conformance (DMARC). Email content security is facilitated through encryption and authentication of message content using S/MIME and/or Transport Layer Security (TLS) with SMTP. This guide is written for the federal agency email administrator, information security specialists and network managers, but contains general recommendations for all enterprise email administrators.

The public comment period **April 29th, 2016**.

## Authority

55 This publication has been developed by NIST in accordance with its statutory responsibilities under the  
56 Federal Information Security Modernization Act (FISMA) of 2014, 44 U.S.C. § 3541 *et seq.*, Public Law  
57 (P.L.) 113-283. NIST is responsible for developing information security standards and guidelines,  
58 including minimum requirements for federal information systems, but such standards and guidelines shall  
59 not apply to national security systems without the express approval of appropriate federal officials  
60 exercising policy authority over such systems. This guideline is consistent with the requirements of the  
61 Office of Management and Budget (OMB) Circular A-130, Section 8b(3), *Securing Agency Information*  
62 *Systems*, as analyzed in Circular A-130, Appendix IV: *Analysis of Key Sections*. Supplemental  
63 information is provided in Circular A-130, Appendix III, *Security of Federal Automated Information*  
64 *Resources*.

65 Nothing in this publication should be taken to contradict the standards and guidelines made mandatory  
66 and binding on federal agencies by the Secretary of Commerce under statutory authority. Nor should  
67 these guidelines be interpreted as altering or superseding the existing authorities of the Secretary of  
68 Commerce, Director of the OMB, or any other federal official. This publication may be used by  
69 nongovernmental organizations on a voluntary basis and is not subject to copyright in the United States.  
70 Attribution would, however, be appreciated by NIST.

73 CODEN: NSPUE2

74 This publication is available free of charge  
75

76 Certain commercial entities, equipment, or materials may be identified in this document in order to describe an  
77 experimental procedure or concept adequately. Such identification is not intended to imply recommendation or  
78 endorsement by NIST, nor is it intended to imply that the entities, materials, or equipment are necessarily the best  
79 available for the purpose.

80 There may be references in this publication to other publications currently under development by NIST in  
81 accordance with its assigned statutory responsibilities. The information in this publication, including concepts and  
82 methodologies, may be used by federal agencies even before the completion of such companion publications. Thus,  
83 until each publication is completed, current requirements, guidelines, and procedures, where they exist, remain  
84 operative. For planning and transition purposes, federal agencies may wish to closely follow the development of  
85 these new publications by NIST.

86 Organizations are encouraged to review all draft publications during public comment periods and provide feedback  
87 to NIST. All NIST Computer Security Division publications, other than the ones noted above, are available at  
88 <http://csrc.nist.gov/publications>.

89 **Comments on this publication may be submitted to [SP800-177@nist.gov](mailto:SP800-177@nist.gov)**

90 **Public comment period: through *November 30, 2015***

## Reports on Computer Systems Technology

97 The Information Technology Laboratory (ITL) at the National Institute of Standards and  
98 Technology (NIST) promotes the U.S. economy and public welfare by providing technical  
99 leadership for the Nation's measurement and standards infrastructure. ITL develops tests, test  
100 methods, reference data, proof of concept implementations, and technical analyses to advance  
101 the development and productive use of information technology. ITL's responsibilities include the  
102 development of management, administrative, technical, and physical standards and guidelines for  
103 the cost-effective security and privacy of other than national security-related information in  
104 federal information systems. The Special Publication 800-series reports on ITL's research,  
105 guidelines, and outreach efforts in information system security, and its collaborative activities  
106 with industry, government, and academic organizations.

107

### Abstract

108 This document gives recommendations and guidelines for enhancing trust in email. The primary  
109 audience includes enterprise email administrators, information security specialists and network  
110 managers. This guideline applies to federal IT systems and will also be useful for any small or  
111 medium sized organizations. Technologies recommended in support of core Simple Mail  
112 Transfer Protocol (SMTP) and the Domain Name System (DNS) include mechanisms for  
113 authenticating a sending domain (Sender Policy Framework (SPF), Domain Keys Identified Mail  
114 (DKIM) and Domain based Message Authentication, Reporting and Conformance (DMARC).  
115 Recommendations for email transmission security include Transport Layer Security (TLS) and  
116 associated certificate authentication protocols. Email content security is facilitated through  
117 encryption and authentication of message content using S/MIME and OpenPGP, and associated  
118 certificate and key distribution protocols.

119

## **Acknowledgements**

127

### **Audience**

128 This document gives recommendations and guidelines for enhancing trust in email. The primary  
129 audience for these recommendations is enterprise email administrators, information security  
130 specialists and network managers. While some of the guidelines in this document pertain to  
131 federal IT systems and network policy, most of the document will be more general in nature and  
132 could apply to any small-mid sized organization.

133 For most of this document, it will be assumed that the organization has some or all responsibility  
134 for email and can configure or manage its own email and Domain Name System (DNS) systems.  
135 Even if this is not the case, the guidelines and recommendations in this document may help in  
136 education about email security and can be used to produce a set of requirements for a contracted  
137 service.

138

### **Note to Reviewers**

139 This document is considered a DRAFT publication. Reviews and comments are welcome and  
140 should be sent via email to SP800-177@nist.gov. The public comment period runs from  
141 MM/DD/YYYY to MM/DD/YYYY.

## 144 **Executive Summary**

145 This document gives recommendations and guidelines for enhancing trust in email. The primary  
146 audience includes enterprise email administrators, information security specialists and network  
147 managers. This guideline applies to federal IT systems and will also be useful for any small or  
148 medium sized organizations.

149 Email is a core application of large-scale computer networking and has been such since the early  
150 days of Internet development. In those early days, networking was a collegial, research-oriented  
151 enterprise. Security was not a consideration. The past forty years have seen diversity in  
152 applications operated over the Internet, and worldwide adoption of email by research  
153 organizations, governments, militaries, businesses and individuals. At the same time there has  
154 been and associated increase in criminal and nuisance threats.

155 The Internet's underlying email protocol was adopted in 1982 and can still be deployed and  
156 operated today. However, this protocol is susceptible to a wide range of attacks including man-  
157 in-the-middle content modification and content surveillance. The basic standards have been  
158 modified and augmented over the years with adaptations that mitigate these threats. With  
159 spoofing protection, content modification protection, encryption and authentication, properly  
160 implemented email can be regarded as sufficiently secure for government, financial and medical  
161 communications.

162 NIST has been active in the development of email security guidelines for many years. The most  
163 recent NIST guideline on secure email includes NIST SP 800-45, Version 2 of February 2007,  
164 *Guidelines on Electronic Mail Security*. The purpose of that document is:

165 "To recommend security practices for designing, implementing and operating email  
166 systems on public and private networks,"

167 Those recommendations include practices for securing the environments around enterprise mail  
168 servers and mail clients, and efforts to eliminate server and workstation compromise. This guide  
169 complements SP800-45 by providing more up-to-date recommendations and guidance for email  
170 signatures and encryption (via S/MIME), recommendations for protecting against unwanted  
171 email (spam), and other aspects of email system deployment and configuration.

172 Following a description of the general email infrastructure and a threat analysis, these guidelines  
173 cluster into techniques for authenticating a sending domain, techniques for assuring email  
174 transmission security and those for assuring email content security. The bulk of the security  
175 enhancements to email rely on records and keys stored in the Domain Name System (DNS) by  
176 one party, and extracted from there by the other party. Increased reliance on the DNS is  
177 permissible because of the security enhancements there, in particular the development and  
178 widespread deployment of the DNS Security Extensions (DNSSEC) to provide authentication  
179 and integrity protection of DNS data.

180 The purpose of authenticating the sending domain is to guard against senders (both random and  
181 malicious actors) from spoofing another's domain and initiating messages with bogus content,  
182 and against malicious actors from modifying message content in transit. Sender Policy

183 Framework (SPF) is the standardized way for a sending domain to identify and assert the mail  
184 senders for a given domain. Domain Keys Identified Mail (DKIM) is the mechanism for  
185 eliminating the possibility of man-in-the-middle content modification by using digital signatures  
186 generated from the sending mail server.

187 Domain based Message Authentication, Reporting and Conformance (DMARC) was conceived  
188 to allow email senders to specify policy on how their mail should be handled, the types of reports  
189 that receivers can send back, and the frequency those reports should be sent. Standardized  
190 handling of SPF and DKIM removes guesswork about whether a given message is authentic,  
191 benefitting receivers by allowing more certainty in quarantining and rejecting inauthentic mail.  
192 In particular, receivers compare the “From” address in the message to the SPF and DKIM  
193 results, if present, and the DMARC policy in the DNS. The results are used to determine how  
194 the mail should be handled. The receiver sends reports to the domain owner about mail claiming  
195 to originate from their domain. These reports should illuminate the extent to which unauthorized  
196 users are using the domain, and the proportion of mail received that is “good.”

197 Eavesdropping and man-in-the-middle attacks can intercept cleartext messages as they are  
198 transmitted hop-by-hop between mail relays. Any bad actor, or organizationally privileged actor,  
199 can read such mail as it travels from submission to delivery systems. Email message  
200 confidentiality can be assured by encrypting traffic along the path. The Transport Layer Security  
201 Protocol (TLS) uses an encrypted channel to obscure message transfers from man-in-the-middle  
202 attacks. TLS relies on the Public Key Infrastructure (PKI) system of X.509 certificates to carry  
203 keying material and provide information about the entity holding the certificate. This is usual  
204 generated by a Certificate Authority. The CA ecosystem has in recent years become the subject  
205 of attack, and has been successfully compromised more than once. One way to protect against  
206 CA compromises is to use the DNS to allow domains to specify the certificates or CAs that the  
207 domain intends to use. Such uses of DNS require that the DNS itself be secured with DNSSEC.  
208 Correctly configured deployment of TLS may not stop a man-in-the-middle from viewing  
209 encrypted traffic, but does practically eliminate the chance of deciphering it.

210 Transport layer encryption also assures the integrity of data in transit, but senders and receivers  
211 who want end-to-end assurance, (i.e. mailbox to mailbox) may wish to implement individual-  
212 level authentication and confidentiality protections. The sender may wish to digitally sign and/or  
213 encrypt the message content, and the receiver can authenticate and/or decrypt the received  
214 message. Secure Multipurpose Internet Mail Extensions (S/MIME) is the recommended protocol  
215 for email authentication and confidentiality. S/MIME is particularly useful for authenticating  
216 mass email mailings originating from mailboxes that are not monitored, since the protocol uses  
217 PKI to authenticate digitally signed messages, avoiding the necessity of distributing the sender’s  
218 public key certificate in advance. However, S/MIME senders need to possess the certificate of  
219 each recipient if the sender wishes to send encrypted mail. Research is underway that will allow  
220 the DNS to be used as a lightweight publication infrastructure for S/MIME certificates.

221 Email communications cannot be made trustworthy with a single package or application. It  
222 involves incremental additions to basic subsystems, with each technology adapted to a particular  
223 task. Some of the techniques use other protocols such as DNS to facilitate specific security  
224 functions like domain authentication, content encryption and message originator authentication.  
225 These can be implemented discretely or in aggregate, according to organizational needs.

## 368 **1 Introduction**

### 369 **1.1 What This Guide Covers**

370 This guide provides recommendations for deploying protocols and technologies that improve the  
371 trustworthiness of email. These recommendations reduce the risk of spoofed email being used as  
372 an attack vector and reduce the risk of email contents being disclosed to unauthorized parties.  
373 These recommendations cover both the email sender and receiver.

374 Several of the protocols discussed in this guide use technologies beyond the core email protocols  
375 and systems. These includes the Domain Name System (DNS), Public Key Infrastructure (PKI)  
376 and other core Internet protocols. This guide discusses how these systems can be used to provide  
377 security services for email.

### 378 **1.2 What This Guide Does Not Cover**

379 As this guide views email as a service, it does not discuss topics such as individual server  
380 hardening, configuration and network planning. These topics are covered in NIST Special  
381 Publication 800-45, Version 2 of February 2007, *Guidelines on Electronic Mail Security* [SP800-  
382 45]. This guide should be viewed as a companion document to SP 800-45 that provides more up-  
383 to-date guidance and recommendations that covers multiple components. This guide attempts to  
384 provide a holistic view of email and will only discuss individual system recommendations as  
385 examples warrant.

386 Likewise, this guide does not give specific configuration details for email components. There  
387 are a variety of hardware and software components that perform one or multiple email related  
388 tasks and it would be impossible to list them all in one guide. This guide will discuss protocols  
389 and configuration in an implementation neutral manner and administrators will need to consult  
390 their system documentation on how to execute the guidance for their specific implementations.

### 391 **1.3 Document Structure**

392 The rest of the document is presented in the following manner:

- 393 • **Section 2:** Discusses the core email protocols and the main components such as Mail  
394 Transfer Agents (MTA) and Mail User Agents (MUA), and cryptographic email formats.  
395
- 396 • **Section 3:** Discusses the threats against an organization's email service such as phishing,  
397 spam and denial of service (DoS).  
398
- 399 • **Section 4:** Discusses the protocols and techniques a sending domain can use to  
400 authenticate valid email senders for a given domain. This includes protocols such as  
401 Sender Policy Framework (SPF), Domain Keying (DKIM) and Domain-based Message  
402 and Reporting Conformance (DMARC).  
403

- 404 • **Section 5:** Discusses server-to-server and end-to-end email authentication and  
405 confidentiality of message contents. This includes email sent over Transport Layer  
406 Security (TLS), Secure Multipurpose Internet Mail Extensions (S/MIME) and OpenPGP.  
407
- 408 • **Section 6:** Discusses technologies to reduce unsolicited and (often) malicious email  
409 messages sent to a domain.  
410
- 411 • **Section 7:** Discusses email security as it relates to end users and the final hop between  
412 local mail delivery servers and email clients. This includes Internet Message Access  
413 Protocol (IMAP), Post Office Protocol (POP3), and techniques for email encryption.  
414

#### 415 **1.4 Conventions Used in this Guide**

416 Throughout this guide, the following format conventions are used to denote special use text:

417 **keyword** - The text relates to a protocol keyword or text used as an example.

418 **Security Recommendation:** - Denotes a recommendation that administrators should note  
419 and account for when deploying the given protocol or security feature.

420 URLs are also included in the text and references to guide readers to a given website or online  
421 tool designed to aid administrators. This is not meant to be an endorsement of the website or any  
422 product/service offered by the website publisher. All URLs were considered valid at the time of  
423 writing.

## 424 2 Elements of Email

### 425 2.1 Email Components

426 There are a number of software components used to produce, send and transfer email. These  
 427 components can be classified as clients or servers, although some components act as both. Some  
 428 components are used interactively, and some are completely automated. In addition to the core  
 429 components, some organizations use special purpose components that provide a specific set of  
 430 security features. There are also other components used by mail servers when performing  
 431 operations. These include the Domain Name System (DNS) and other network infrastructure  
 432 pieces.

433 Fig 2-1 shows the relationship between the email system components on a network, which are  
 434 described below in greater detail.

435

436

Fig 2-1: Main Components Used for Email

#### 437 2.1.1 Mail User Agents (MUAs)

438 Most end users interact with their email system via a Mail User Agent (MUA). A MUA is a  
 439 software component that allows an end user to compose and email message and send it to one or  
 440 more recipients. The message is then sent to a server for further processing (either final delivery  
 441 or transfer to another server). The MUA is also the component used by end users to access a  
 442 mailbox where emails have been delivered. MUAs are available for a variety of systems  
 443 including mobile hosts. The proper secure configuration for an MUA depends on the MUA in  
 444 question and the system it is running on. Some basic recommendations can be found in Section  
 445 7.

446 MUAs may utilize several protocols to connect to and communicate with email servers, (see  
 447 Section below). There may also be other features as well such as a cryptographic interface for  
 448 producing encrypted and/or digitally signed email.

### 449 **2.1.2 Mail Transfer Agents (MTAs)**

450 Email is transmitted across networks via Mail Transfer Agents (MTAs). MTAs communicate  
451 using the Simple Mail Transfer Protocol (SMTP) described below and act as both client and  
452 server, depending on the situation. For example, an MTA can act as a server when accepting an  
453 email message from an end user's MUA, then act as a client in connecting to and transferring the  
454 message to the recipient domain's MTA for final delivery.

455 MTAs can be described with more specialized language that denotes specific functions:

- 456 • **Mail Submission Agents (MSA):** An MTA that accepts mail from MUAs and begins the  
457 transmission process by sending it to a MTA for further processing. Often the MSA and  
458 first-hop MTA is the same process, just fulfilling both roles.  
459
- 460 • **Mail Delivery Agent (MDA):** An MTA that receives mail from an organization's  
461 inbound MTA and ultimately places the message in a specific mailbox. Like the MSA,  
462 the MDA could be a combined in-bound MTA and MDA component.  
463

464 MTAs may also perform various security functions to prevent malicious email from being  
465 delivered or include authentication credentials such as digital signatures (see Section 4.4,  
466 Domain Keys Identified Mail (DKIM), and Section 4.3). These security functions may be  
467 provided by other components that act as lightweight MTAs or these functions may be added to  
468 MTAs via filters or patches.

### 469 **2.1.3 Special Use Components**

470 In addition to MUAs and MTAs, an organization may use one or more special purpose  
471 components for a particular task. These components may provide a security function such as  
472 malware filtering, or may provide some business process functionality such as email archiving or  
473 content filtering. These components may exchange messages with other parts of the email  
474 infrastructure using part or all of the Simple Mail Transfer Protocol (see below) or use another  
475 protocol altogether.

476 Given the variety of components, there is no one single set of configurations for an administrator  
477 to deploy, and different organizations have deployed very different email architectures. An  
478 administrator should consult the documentation for their given component and their existing site-  
479 specific documentation.

### 480 **2.1.4 Special Considerations for Cloud and Hosted Service Customers**

481 Organizations that outsource their email service (whole or in part) may not have direct access to  
482 MTAs or any possible special use components. In cases of Email as a Service (EaaS), the service  
483 provider is responsible for the email infrastructure. Customers of Infrastructure as a Service  
484 (IaaS) may have sufficient access privileges to configure their email servers themselves. In  
485 either set-up, the enterprise may have complete configuration control over MUAs in use.

## 486 **2.1.5 Email Server and Related Component Architecture**

487 How an organization architects its email infrastructure is beyond the scope of this document. It  
488 is up to the organization and administrators to identify key requirements (availability, security,  
489 etc.) and available product or service offerings to meet those requirements. Federal IT  
490 administrators also need to take relevant federal IT policies into account when acquiring and  
491 deploying email systems.

492 Guidance for deploying and configuring a MTA for federal agency use exists as NIST SP 800-45  
493 "Guidelines on Electronic Mail Security" [SP800-45]. In addition, the Dept. of Homeland  
494 Security (DHS) has produced the Email Gateway Reference Architecture [REFARCH] for  
495 agencies to use as a guide when setting up or modifying the email infrastructure for an agency.

## 496 **2.2 Related Components**

497 In addition to MUAs and MTAs, there are other network components used to support the email  
498 service for an organization. Most obviously is the physical infrastructure: the cables, wireless  
499 access points, routers and switches that make up the network. In addition, there are network  
500 components used by email components in the process of completing their tasks. This includes  
501 the Domain Name System, Public Key Infrastructure, and network security components that are  
502 used by the organization.

### 503 **2.2.1 Domain Name System**

504 The Domain Name System (DNS) is a global, distributed database and associated lookup  
505 protocol. DNS is used to map a piece of information (most commonly an IP address) to a human  
506 readable domain name. The DNS is used by MUAs and MTAs to find the address of the next-  
507 hop server for mail delivery. Sending MTAs query DNS for the Mail Exchange Resource  
508 Record (MX RR) of the recipient's domain (the right hand side of the "@" symbol) in order to  
509 find the receiving MTA to contact.

510 In addition to the forward DNS (translate domain names to IP addresses or other data), there is  
511 also the DNS reverse tree that is used to store information that is queried for using an IP address.  
512 Traditionally, the reverse tree to obtain the domain name for a given client based on the source  
513 IP of the connection, but it is also used as a crude, highly imperfect authentication check. A host  
514 compares the forward and reverse DNS trees to check that the remote connection is likely valid  
515 and not a potential attacker abusing a valid IP address block. This can be more problematic in  
516 IPv6, where even small networks can be assigned very large address blocks. Email anti-abuse  
517 consortiums recommend that enterprises should make sure that DNS reverse trees identify the  
518 authoritative mail servers for a domain [M3AAWG].

519 The DNS is also used as the publication method for protocols designed to protect email and  
520 combat malicious, spoofed email. Technologies such as Sender Policy Framework (SPF),  
521 DomainKeying Internet Mail (DKIM) and other use the DNS to publish policy artifacts or public  
522 keys that can be used by receiving MTAs to validate that a given message originated from the  
523 sending domain's mail servers. These protocols are discussed in Section 4. In addition, there are  
524 new proposals to encode end-user certificates (for S/MIME or OpenPGP) in the DNS using a  
525 mailbox as the hostname. These protocols are discussed in Section 5.3.

526 A third use of the DNS with email is with reputation services. These services provide  
527 information about the authenticity of an email based on the purported sending domain or  
528 originating IP address. These services do not rely on the anti-spoofing techniques described  
529 above but through historical monitoring, domain registration history, and other information  
530 sources. These services are often used to combat unsolicited bulk email (i.e. spam) and  
531 malicious email that could contain malware or links to subverted websites.

532 The Domain Name System Security Extensions (DNSSEC) [RFC4033] provides cryptographic  
533 security for DNS queries. Without security, DNS can be subjected to a variety of spoofing and  
534 man-in-the-middle attacks. Recommendations for deploying DNS in a secure manner are beyond  
535 the scope of this document. Readers are directed to NIST SP 800-81 [SP800-81] for  
536 recommendations on deploying DNSSEC.

### 537 **2.2.2 Enterprise Perimeter Security Components**

538 Organizations may utilize security components that do not directly handle email, but may  
539 perform operations that affect email transactions. These include network components like  
540 firewalls, Intrusion Detection Systems (IDS) and similar malware scanners. These systems may  
541 not play any direct role in the sending and delivering of email but may have a significant impact  
542 if misconfigured. This could result in legitimate SMTP connections being denied and the failure  
543 of valid email from being delivered. Network administrators should take the presence of these  
544 systems into consideration when making changes an organization's email infrastructure.

### 545 **2.2.3 Public Key Infrastructure (PKIX)**

546 Organizations that send and receive S/MIME or OpenPGP protected messages will also need to  
547 rely on the certificate infrastructure used with these protocols. The certificate infrastructure does  
548 not always require the deployment of a dedicated system, but does require administrator time to  
549 obtain, configure and distribute security credentials to end-users.

550 S/MIME uses X.509 certificates [RFC5280] to certify and store public keys used to validate  
551 digital signatures and encrypt email. The Internet X.509 Public Key Infrastructure Certificate  
552 and Certificate Revocation List (CRL) Profile is commonly called PKIX and is specified by  
553 [RFC5280]. Certificate Authorities (CA) (or the organization itself) issues X.509 certificates for  
554 an individual end-user or role that sends email (for S/MIME). Separately, X.509 certificates can  
555 also be used to authenticate one or both ends of a TLS connection when SMTP runs over TLS  
556 (MUA to MTA or MTA to MTA). Recommendations for S/MIME protected email are given in  
557 Section 5. Recommendations for SMTP over TLS are given in Section 5. Federal agency  
558 network administrators should also consult NIST SP 800-57 Part 3 [SP800-57P3] for further  
559 guidance on cryptographic parameters and deployment of any PKI components and credentials  
560 within an organization.

## 561 **2.3 Email protocols**

562 There are two types of protocols used in the transmission of email. The first are the protocols  
563 used to transfer messages between MTAs and their end users (using MUAs). The second is the  
564 protocol used to transfer messages between mail servers.

565 This guide is not meant to be an in-depth discussion of the protocols used in email. The  
566 protocols discussed here simply for background information.

### 567 2.3.1 Simple Mail Transfer Protocol (SMTP)

568 Email messages are transferred from one mail server to another (or from an MUA to  
569 MSA/MTA) using the Simple Mail Transfer Protocol (SMTP). SMTP was originally specified  
570 in 1982 as RFC 821 and has undergone several revisions, the most current being RFC 5321  
571 [RFC5321]. SMTP is a text-based client-server protocol where client (email sender) contacts the  
572 server (next-hop recipient) and issues a set of commands to tell the server about the message to  
573 be sent, then sending the message itself. The majority of these commands are ASCII text  
574 messages sent by the client and a resulting return code (and additional ASCII text) returned by  
575 the server. The basic SMTP connection procedure is shown below in Fig 2-2:

```

576 Client connects to port 25
577 Server: 220 mx.example.com
578 Client: HELO mta.example.net
579 S: 250 Hello mta.example.net, I am glad to meet you
580 C: MAIL FROM:<alice@example.org>
581 S: 250 Ok
582 C: RCPT TO:<bob@example.com>
583 S: 354 End data with <CR><LF>.<CR><LF>
584 Client sends message headers and body
585 C: .
586 S: 250 Ok: queued as 12345
587 C: QUIT
588 S: 221 Bye
589 Server closes the connection

```

590 **Fig 2-2: Basic SMTP Connection Set-up**

591 In the above, the client initiates the connection using TCP over port 25<sup>1</sup>. After the initial  
592 connection the client and server perform a series of SMTP transactions to send the message.  
593 These transactions take the form of first stating the return address of the message (known as the  
594 return path) using the **MAIL** command, then the recipient(s) using the **RCPT** command and ending  
595 with the **DATA** command which contains the header and body of the email message. After each  
596 command the server response with either a positive or negative (i.e. error) code.

597 SMTP servers can advertise the availability of options during the initial connection. These  
598 extensions are currently defined in RFC 5321 [RFC5321]. These options usually deal with the  
599 transfer of the actual message and will not be covered in this guide except for the STARTTLS  
600 option. This option given by the server is used to indicate to the client that Transport Layer

---

<sup>1</sup> Although MUAs often use TCP port 587 when submitting email to be sent.

601 Security (TLS) is available. SMTP over TLS allows the email message to be sent over an  
602 encrypted channel to protect against monitoring a message in transit. Recommendations for  
603 configuring SMTP over TLS are given in Section 5.2.

### 604 **2.3.2 Mail Access Protocols (POP3, IMAP, MAPI/RPC)**

605 MUAs typically do not use SMTP when retrieving mail from an end-user's mailbox. MUAs use  
606 another client-server protocol to retrieve the mail from a server for display on an end-user's host  
607 system. These protocols are commonly called Mail Access Protocols and are either Post Office  
608 Protocol (POP3) or Internet Message Access Protocol (IMAP). Most modern MUAs support  
609 both protocols but an enterprise service may restrict the use of one in favor of a single protocol  
610 for ease of administration or other reasons. Recommendations for the secure configuration of  
611 these protocols are given in Section 7.

612 POP3 [STD35] is the simpler of the two protocols and typically downloads all mail for a user  
613 from the server, then deletes the copy on the server, although there is an option to maintain it on  
614 the server. POP3 is similar SMTP, in that the client connects to a port (normally port 110 or port  
615 995 when using TLS) and sends ASCII commands, to which the server responds. When the  
616 session is complete, the client terminates the connection. POP3 transactions are normally done  
617 in the clear, but an extension is available to do POP3 over TLS using the STLS command, which  
618 is very similar to the STARTTLS option in SMTP. Clients may connect initially over port 110  
619 and invoke the STLS command, or alternatively, most servers allow TLS by default connections  
620 on port 995.

621 IMAP [RFC3501] is an alternative to POP3 but includes more built-in features that make it more  
622 appealing for enterprise use. IMAP clients can download email messages, but the messages  
623 remain on the server. This and the fact that multiple clients can access the same mailbox  
624 simultaneously mean that end-users with multiple devices (laptop and smartphone for example),  
625 and keep their email synchronized across multiple devices. Like POP3, IMAP also has the  
626 ability to secure the connection between a client and a server. Traditionally, IMAP uses port 143  
627 with no encryption. Encrypted IMAP runs over port 993, although modern IMAP servers also  
628 support the STARTTLS option on port 143.

629 In addition to POP3 and IMAP, there are other proprietary protocols in use with certain  
630 enterprise email implementations. Microsoft Exchange clients<sup>2</sup> can use the Messaging  
631 Application Programming Interface (MAPI/RPC) to access a mailbox on a Microsoft Exchange  
632 server (and some other compatible implementations). Some cloud providers require clients to  
633 access their cloud-based mailbox using a web portal as the MUA instead of a dedicated email  
634 client. With the exception of Microsoft's Outlook Web Access, most web portals use IMAP to  
635 access the user's mailbox.

---

<sup>2</sup> Administrators should consult their implementation's version-specific documentation on the correct security configuration.

## 636 2.4 Email Formats

637 Email messages may be formatted as plain text or as compound documents containing one or  
638 more components and attachments. Modern email systems layer security mechanisms on top of  
639 these underlying systems.

### 640 2.4.1 Email Message Format: Multi-Purpose Internet Mail Extensions (MIME)

641 Internet email was originally sent as plain text ASCII messages [RFC2822]. The Multi-purpose  
642 Internet Mail Extensions (MIME) [RFC2045][RFC2046][RFC2047] allows email to contain  
643 non-ASCII character sets as well as other non-text message components and attachments.  
644 Essentially MIME allows for an email message to be broken into parts, with each part identified  
645 by a content type. Typical content types include `text/plain` (for ASCII text), `image/jpeg`,  
646 `text/html`, etc. A mail message may contain multiple parts, which themselves may contain  
647 multiple parts, allowing MIME-formatted messages to be included as attachments in other  
648 MIME-formatted messages. The available types are listed in an IANA registry<sup>3</sup> for developers,  
649 but not all may be understood by all MUAs.

### 650 2.4.2 Security in MIME Messages (S/MIME)

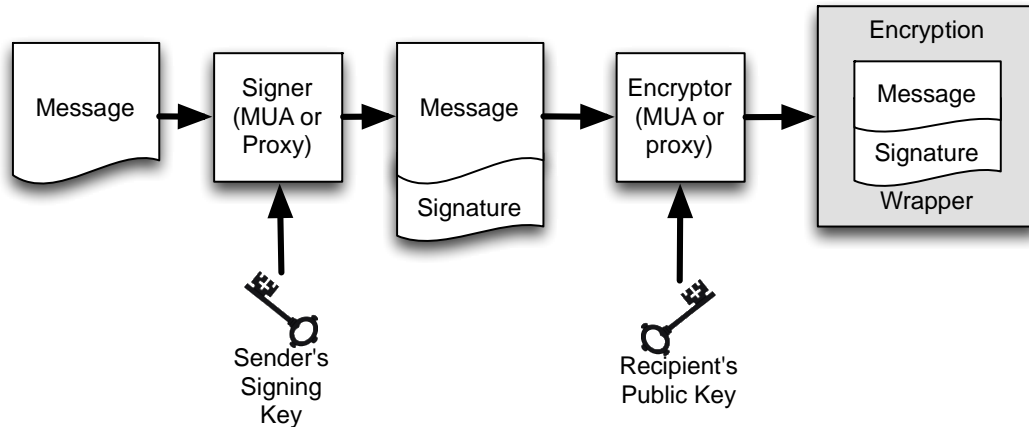

651 The Secure Multi-purpose Internet Mail Extensions (S/MIME) is a set of widely implemented  
652 proposed Internet standards for cryptographically securing email [RFC5750][RFC5751].  
653 S/MIME provides authentication, integrity and non-repudiation (via digital signatures) and  
654 confidentiality (via encryption). S/MIME utilizes asymmetric keys for cryptography (i.e. public  
655 key cryptography) where the public portion is normally encoded and presented as X.509 digital  
656 certificates.

657 With S/MIME, signing digital signatures and message encryption are two distinct operations:  
658 messages can be digitally signed, encrypted, or both digitally signed *and* encrypted (Fig 2-5).  
659 Because the process is first to sign and then encrypt, S/MIME is vulnerable to re-encryption  
660 attacks<sup>4</sup>; a protection is to include the name of the intended recipient in the encrypted message.

---

<sup>4</sup> Don Davis. 2001. Defective Sign & Encrypt in S/MIME, PKCS#7, MOSS, PEM, PGP, and XML. In *Proceedings of the General Track: 2001 USENIX Annual Technical Conference*, Yoonho Park (Ed.). USENIX Association, Berkeley, CA, USA, 65-78.

661

662

Fig 2-5: S/MIME Messages can be signed, encrypted, or both signed and encrypted

663

### 2.4.3 Pretty Good Privacy (PGP/OpenPGP)

664 OpenPGP [RFC3156][RFC4880] is an alternative proposed Internet standard for digitally  
 665 signing and encrypting email. OpenPGP is an adaption of the message format implemented by  
 666 the Pretty Good Privacy (PGP) email encryption system that was first released in 1991. Whereas  
 667 the PGP formats were never formally specified, OpenPGP specifies open, royalty-free formats  
 668 for encryption keys, signatures, and messages. Today the most widely used implementation of  
 669 OpenPGP is Gnu Privacy Guard (gpg)<sup>5</sup>, an open source command-line program that runs on  
 670 many platforms. Most desktop and web-based applications that allow users to send and receive  
 671 OpenPGP-encrypted mail rely on gpg as the actual cryptographic engine.

672

OpenPGP provides similar functionality as S/MIME, with two significant differences:

673

674

675

676

677

678

679

680

681

682

683

684

685

686

687

- **Key Certification:** Whereas X.509 certificates are issued by Certificate Authorities (or local agencies that have been delegated authority by a CA to issue certificates), users generate their own OpenPGP public and private keys and then solicit signatures for their public keys from individuals or organizations to which they are known. Whereas X.509 certificates can be signed by a single party, OpenPGP public keys can be signed by any number of parties. Whereas X.509 certificates are trusted if there is a valid PKIX chain to a trusted root, an OpenPGP public key is trusted if it is signed by another OpenPGP public key that is trusted by the recipient. This is called the “Web-of-Trust.”
- **Key Distribution:** OpenPGP does not include the sender’s public key with each message, so it is necessary for recipients to of OpenPGP-messages to separately obtain the sender’s public key in order to verify the message. Many organizations post OpenPGP keys on SSL-protected websites: people who wish to verify digital signatures or send these organizations encrypted mail need to manually download these keys and add them to their OpenPGP clients. Keys may also be registered with the OpenPGP

<sup>5</sup> <https://www.gnupg.org/>

688 “public key servers” (described below). OpenPGP “public key servers” are computers that  
 689 maintain a database of PGP public keys organized by email address. Anyone may post a  
 690 public key to the OpenPGP key servers, and that public key may contain any email  
 691 address. There is no vetting of OpenPGP keys, so it is trivial for an attacker to submit a  
 692 fraudulent certificate. Such certificates can provide a legitimate name and an incorrect  
 693 email address, possibly tricking sender into using it to send mail to an attacker instead of  
 694 (or addition to) the intended recipient. Alternatively, spoofed certificates can have a  
 695 legitimate name and email address, and a fraudulent key, causing the sender to encrypt a  
 696 message so that it cannot be read by the intended recipient but can be read by the  
 697 attacker.

698 In theory the Web-of-Trust minimizes the problems of the key servers—an OpenPGP user can  
 699 simply download *all* of the keys associated with a particular email address and use the Web of  
 700 Trust to decide which keys to Trust. Because Web-of-Trust supports arbitrary validation  
 701 geometries, it allows both the top-down certification geometry of X.509 as well as peer-to-peer  
 702 approaches. In practice, users find this process confusing, and the Web-of-Trust has not seen  
 703 widespread adoption.

704 An alternative way to publish OpenPGP keys using the DNS is described in Section 5.3,  
 705 although the technique has not been widely adopted.

706 Like S/MIME, one of the biggest hurdles of deploying OpenPGP has been the need for users to  
 707 create certificates in advance and the difficulty of obtaining the certificate of another user in  
 708 order to send an encrypted message. However, in OpenPGP this difficulty impacts both digital  
 709 signatures and encryption, since OpenPGP messages do not include the sender’s digital  
 710 certificate in the signature.

711 These differences are summarized in Table 2-1.

712 **Table 2-1: Comparison of S/MIME and OpenPGP operations**

Action	S/MIME	OpenPGP
Key creation	Users obtain X.509 certificates from employer (e.g. a US Government PIV card) or a Certificate Authority	Users make their own public/private key pairs and have them certified by associates.
Certificate Verification	PKIX: Certificates are verified using trusted roots that are installed on the end user’s computer.	Web-of-Trust: Keys can be signed by any number of certifiers. Users base their trust decisions on whether or not they “trust” the keys that were used to sign the key.
Certificate Revocation	Certificates can be revoked by the CA or Issuer	Certificates can only be revoked by the public key’s owner.

Obtaining public keys	Querying an LDAP server or exchanging digitally signed email messages.	PGP public key server or out-of-band mechanisms (e.g. posting a public key on a web page.)
-----------------------	------------------------------------------------------------------------	--------------------------------------------------------------------------------------------

### 713 **3 Security Threats to an Email Service**

714 The security threats to email service discussed in this section are related to canonical functions of  
 715 the service such as: message submission (at the sender end), message transmission (transfer) and  
 716 message delivery (at the recipient end).

717 Threats to the core email infrastructure functions can be classified as follows:

- 718 • **Integrity-related threats to the email system**, which could result in unauthorized access  
 719 to an enterprises' email system.
- 720 • **Confidentiality-related threats to email**, which could result in unauthorized disclosure  
 721 of sensitive information.
- 722 • **Availability-related threats to the email system**, which could prevent end users from  
 723 being able to send or receive email.

724 The security threats due to insufficiency of core security functions are not covered. These  
 725 include threats to support infrastructure such as network components and firewalls, host OS and  
 726 system threats, and potential attacks due to lax security policy at the end user or administrator  
 727 level (e.g., poor password choices). Threats directed to these components and recommendations  
 728 for enterprise security policies are found in other documents.

#### 729 **3.1 Integrity-related Threats**

730 Integrity in the context of an email service assumes multiple dimensions. Each dimension can be  
 731 the source of one or more integrity-related threats:

- 732 • Unauthorized email senders in a valid IP address block
- 733 • Unauthorized email receivers
- 734 • Unauthorized email messages from a valid DNS domain
- 735 • Tampering/Modification of email content from a valid DNS domain
- 736 • Emails to/from hijacked domains
- 737 • Phishing and spear phishing

##### 738 **3.1.1 Unauthorized Email Senders within an organization's IP address block**

739 An unauthorized email sender is some MTA that sends email message that appear to be from a  
 740 specific domain (e.g. "user@example.com"), but is not identified as a legitimize mail sender by  
 741 the organization that runs the domain.

742 The main risk that an unauthorized email sender may pose to an enterprise is that a sender may  
 743 be sending malicious email and using the enterprise's IP address block and reputation to avoid  
 744 anti-spam filters. A related risk is that the sender may be sending emails that represent  
 745 themselves as legitimate communications from the enterprise itself.

746 There are many scenarios that might result in an unauthorized email sender:

- 747
- 748
- 749
- 750
- 751
- Malware present on an employee’s laptop may be sending out email without the employee’s knowledge.
  - An employee may configure and operate a mail server without authorization.
  - A device such as a photocopier or an embedded system may contain a mail sender that is sending mail without anyone’s knowledge.

752 One way to mitigate the risk of unauthorized senders is for the enterprise to block outbound port  
753 25 (used by SMTP) for all hosts except those authorized to send mail. In addition, domains can  
754 deploy sender authentication mechanisms like those described in Section 4, “Authenticating a  
755 Sending Domain and Individual Mail Messages” that can help senders to determine if the mail  
756 they received came from an unauthorized source.

757 **Security Recommendation 3-1:** To mitigate the risk of unauthorized sender, an enterprise  
758 administrator should block outbound port 25 and look to deploy firewall or intrusion detection  
759 systems (IDS) that can alert the administrator when an unauthorized host is sending mail via  
760 SMTP to the Internet.

761 The proliferation of virtualization greatly increases the risk that an unauthorized virtual server  
762 (Virtual Machines or VMs) within a particular enterprise might send email. This is because many  
763 VMs are configured by default to run email servers (MTAs), and many VM hypervisors use  
764 network address translation (NAT) to share a single IP address between multiple VMs. Thus, a  
765 VM that is unauthorized to send email may share an IP address with a legitimate email sender.  
766 To prevent such a situation, ensure that VMs that are authorized mail senders and those VMs that  
767 are not do not share outbound IP addresses. An easy way to do this is assigning these VMs to  
768 different NAT instances. Alternatively, internal firewall rules can be used to block outbound port  
769 25 for VMs that are not authorized to send email.

770 **Security Recommendation 3-2:** Virtual Machines that are not involved in the organization’s  
771 email infrastructure should be configured to not run Mail Transfer Agents (MTAs).

### 772 3.1.2 Unauthorized Email Receiver Within an Organization’s IP Address Block

773 Unauthorized mail receivers are a risk to the enterprise IT security posture because they may be  
774 an entry point for malicious email. If the enterprise email administrator does not know of the  
775 unauthorized email receiver, they cannot guarantee the server is secure and provides the  
776 appropriate mail handling rules for the enterprise such as scanning for malicious links/code,  
777 filtering spam, etc. This could allow malware to bypass the enterprise DMZ and enter the local  
778 network undetected.

779 **Security Recommendation 3-3:** To mitigate the risk of unauthorized receivers, an enterprise  
780 administrator should block inbound port 25 and look to deploy firewall or intrusion detection  
781 systems (IDS) that can alert the administrator when an unauthorized host is accepting mail via  
782 SMTP from the Internet.

### 783 3.1.3 Unauthorized Email Messages from a Valid DNS Domain (Address Spoofing)

784 Just as organizations face the risk that they might have unauthorized email senders, organizations  
785 also face the risk that they might receive email from an unauthorized sender. This is sometimes

786 called “spoofing,” especially when one group or individual sends mail that appears to come from  
787 another. In a spoofing attack, the adversary spoofs messages on another (sometimes even non-  
788 existent) user’s behalf.

789 For example, an attacker sends emails that purport to come from user@example.com, when in  
790 fact the email messages are being sent from a compromised home router. Spoofing the From:  
791 address is trivial, as the SMTP protocol [RFC2821] allows clients to set any From: address.  
792 Alternatively, the adversary can simply configure a MUA with the name and email address of the  
793 spoofed user and send the email to an open SMTP relay (see [RFC2505] for a discussion of open  
794 relays).

795 The same malicious configuration activity can be used to configure and use wrong display  
796 names. When a display name that creates a degree of trust such as “Administrator” shows up on  
797 the email received at the recipient’s end, it might make the recipient reveal some sensitive  
798 information which the recipient will not normally do. Thus the spoofing threat/attack also has a  
799 social engineering aspect as well.

800 Section 4, “Authenticating a Sending Domain and Individual Mail Messages” discusses a variety  
801 of countermeasures for this type of threat. The first line of defense is to deploy domain-based  
802 authentication mechanisms. These mechanisms can be used to alert or block email that was sent  
803 using a spoofed domain. Another end-to-end security technique is to use digital signatures to  
804 provide integrity for message content and since the issue here is the email address of the sender,  
805 the digital signature used should cover the header portion of the email message that contains the  
806 address of the sender.

#### 807 **3.1.4 Tampering/Modification of Email Content**

808 The content of an email message, just like any other message content traveling over the Internet,  
809 is liable to be altered in transit. Hence the content of the received email may not be the same that  
810 was in the sender’s email. The countermeasure for this threat is of course a means to verify the  
811 integrity of the content of each email message that is received.

812 There are several solutions available to mitigate this risk by either encrypting email messages  
813 between servers using Transport Layer Security (TLS) for SMTP or using an end-to-end solution  
814 to encrypt email between initial sender and final receiver. Recommendations for using TLS with  
815 SMTP are discussed in Section 5.2.1, “TLS Configuration and Use,” and end-to-end email  
816 encryption protocols are discussed in Section 5.3, “Email Content Security.”

#### 817 **3.1.5 Emails to/from Hijacked Domains (Pharming attack on DNS resolvers)**

818 Email systems rely on DNS for many functions. Some of them are:

- 819 • The sending MTA uses the DNS to find the IP address of the recipient email server for all  
820 outgoing emails if the To: address of the email is located in a different domain.
- 821 • The recipient email server (if built with the feature) uses the DNS to look for appropriate  
822 records in the sending DNS domain either to authenticate the sending email server (SPF)

823 or to authenticate an email message for its origin domain (DKIM). See Section 5 for  
824 details.

825 The threat in using a DNS infrastructure without security even in a small portion of its hierarchy  
826 is that a DNS response can be spoofed and can potentially return the IP address desired by an  
827 attacker, rather than the legitimate IP address of a queried domain name. In theory, this allows  
828 email messages to be redirected, intercepted, or spoofed.

829 The DNSSEC security extension [RFC4033][RFC4034] [RFC4035] can provide protection from  
830 pharming attacks since it ensures the data origin through an authentication chain from the root to  
831 the resolver. However, even the presence of a single non-DNSSEC resolver can compromise the  
832 integrity of the DNS query response.

### 833 **3.1.6 Phishing and Spear Phishing**

834 Phishing is the process of illegal collection of private/sensitive information using a spoofed  
835 email as the means. This is done with the intention of committing identity theft, gaining access to  
836 credit cards and bank accounts of the victim etc. Adversaries use a variety of several tactics to  
837 make the recipient of the email into believing that they have received the phishing email from a  
838 legitimate user or a legitimate domain, including:

- 839 • Using a “From” address that looks very close to one of the legitimate addresses the user  
840 is familiar with or from someone claiming to be an authority (IT administrator, manager,  
841 etc.).
- 842 • Presenting to the recipient an alarm, a financial lure, or otherwise attractive situation, that  
843 either makes the recipient panic or tempts the recipient into taking an action or providing  
844 requested information.
- 845 • Sending the email from an email using a legitimate account holder’s software or  
846 credentials, typically using a bot that has taken control of the email client or malware that  
847 has stolen the user’s credentials (described in detail in Section 3.3.1 below)

848 As part of the email message, the recipient may is asked to click on a link to what appears like a  
849 legitimate website, but in fact is a URL that will take the recipient into a spoofed website set up  
850 by the adversary. On clicking in, the victim may also find that the sign-in page, logos and  
851 graphics are identical to the legitimate website in the adversary-controlled website, thereby  
852 creating the trust necessary to make the recipient submit the required information such as user ID  
853 and the password. Some attackers use web pages to deliver software exploits directly to the  
854 victim’s web browser.

855 In many instances, the phishing emails are generated in thousands without focus on profile of the  
856 victims. Hence they will have a generic greeting such as “Dear Member”, “Dear Customer” etc.  
857 A variant of phishing is spear phishing where the adversary is aware and specific about the  
858 victim’s profile. More than a generic phishing email, a spear phishing email makes use of more  
859 context information to make users believe that they are interacting with a legitimate content. For  
860 example, a spear phishing email may appear to relate to some specific item of personal  
861 importance or a relevant matter at the organization –for instance, discussing payroll

862 discrepancies or a legal matter. As in phishing, the ultimate motive is the same – to lure the  
863 recipient to an adversary-controlled website faking as a legitimate website to collect sensitive  
864 information about the victim or attack the victim’s computer.

865 There are two minor variations of phishing: clone phishing and whaling. Clone phishing is the  
866 process of cloning an email from a legitimate user carrying an attachment or link and then  
867 replacing the link or attachment alone with a malicious version and then sending the same from  
868 an email address spoofed to appear to come from the original sender (carrying the pretext of re-  
869 sending or sending an updated version). Whaling is a type of phishing specifically targeted  
870 against high profile targets so that the resulting damage carries more publicity and/or financial  
871 rewards for the perpetrator is more.

872 The most common countermeasure used against phishing is to design anti-phishing filters that  
873 can detect text commonly used in phishing emails, recovering hidden text in images, intelligent  
874 word recognition – detecting cursive, hand-written, rotated or distorted texts as well as the ability  
875 to detect texts on colored backgrounds.

### 876 **3.2 Confidentiality-related Threats**

877 A confidentiality-related threat occurs when the data stream containing email messages with  
878 sensitive information are accessible to an adversary. The type of attack that underlies this threat  
879 is passive since the adversary has read access but not write access to the email data being  
880 transmitted. There are two variations of this type of attack include:

- 881 • The adversary may have access to the packets that make up the email message as they move  
882 over a network. This access may come in the form of a passive wiretapping or eavesdropping  
883 attack.
- 884 • Software may be installed on a MTA that makes copies of email messages and delivers them  
885 to the adversary. For example, the adversary may have modified the target’s email account so  
886 that a copy of every received message is forwarded to an email address outside the  
887 organization.

888 Encryption is the best defense against eavesdropping attacks. Encrypting the email messages  
889 either between MTAs (using TLS as described in Section 5) can thwart attacks involving packet  
890 interception. End-to-end encryption (described in Section 5.3) can protect against both  
891 eavesdropping attacks as well as MTA software compromise.

892 A second form of passive attack is a traffic analysis attack. In this scenario, the adversary is not  
893 able to directly interpret the contents of an email message, mostly due to the fact that the  
894 message is encrypted. However, since inference of information is still possible in certain  
895 circumstances (depending upon interaction or transaction context) from the observation of  
896 external traffic characteristics (volume and frequency of traffic between any two entities) and  
897 hence the occurrence of this type of attack constitutes a confidentiality threat.

898 Although the impact of traffic analysis is limited in scope, it is much easier to perform this attack

899 in practice—especially if part of the email transmission media uses a wireless network, if packets  
900 are sent over a shared network, or if the adversary has the ability to run network management or  
901 monitoring tools against the victim’s network. TLS encryption provides some protection against  
902 traffic analysis attacks, as the attacker is prevented from seeing any message headers. End-to-end  
903 email encryption protocols do not protect message headers, as the headers are needed for  
904 delivery to the destination mailbox. Thus, organizations may wish to employ both kinds of  
905 encryption to secure email from confidentiality threats.

### 906 **3.3 Availability-related Threats**

907 An availability threat exists in the email infrastructure (or for that matter any IT infrastructure),  
908 when potential events occur that prevents the resources of the infrastructure from functioning  
909 according to their intended purpose. The following availability-related threats exist in an email  
910 infrastructure.

- 911 • Email bombing and unsolicited bulk email (i.e. spam)
- 912 • Availability of email servers

#### 913 **3.3.1 Email Bombing and Spam**

914 “Email bombing” is a type of denial of service attack (DoS). A DoS attack by definition either  
915 prevents authorized access to resources or causes delay (e.g., long response times) of time-  
916 critical operations. Hence email bombing is a major availability threat to an email system since it  
917 can potentially consume substantial Internet bandwidth as well as storage space in the message  
918 stores of recipients. An email bombing attack can be launched in several ways.

919 There are many ways to perpetrate an email bombing attack, including:

- 920 • An adversary can employ any (anonymous) email account to constantly bombard the victim’s  
921 email account with arbitrary messages (that may contain very long attachments).
- 922 • If an adversary controls an MTA, the adversary can run a program that automatically  
923 composes and transmits messages.
- 924 • An adversary can post a controversial or official statement to a large audience (e.g., a social  
925 network) using the victim’s return email address. Humans will read the message and respond  
926 with individually crafted messages that may be very hard to filter with automated techniques.  
927 The responses to this posting will eventually flood the victim’s email account.
- 928 • An adversary may subscribe the victim’s email address to many mailing lists (“listservers”).  
929 The generated messages are then sent to the victim, until the victim’s email address is  
930 unsubscribed from those lists.

931 Spam refers to indiscriminately sent messages that are unsolicited, unwanted, irrelevant and/or  
932 inappropriate, such as commercial advertising in mass quantities. Spam that targets particular  
933 users or groups of users is called phishing. From the above discussion of email bombing attacks,  
934 it should be clear that spam is one type email bombing.

937 Protecting the email infrastructure against spam is a challenging problem. This is due to the fact  
 938 that the two types of techniques currently used to combat spam have limitations. See Section 6  
 939 for a more detailed discussion of unsolicited bulk email.

### 940 3.3.2 Availability of Email Servers

941 The email infrastructure just like any other IT infrastructure should provide for fault tolerance  
 942 and avoid single point of failure. A domain with only a single email server or a domain with  
 943 multiple email servers, but all located in a single IP subnet is likely to encounter availability  
 944 problems either due to software glitches in MTA, hardware maintenance issues or data center  
 945 network problems. The due diligence measures for ensuring high availability of email servers  
 946 are: (a) Multiple numbers of them, based on the email traffic load encountered by the enterprise  
 947 and (b) Distribution of Email servers in different network segments or even physical locations.

### 948 3.4 Summary of Threats and Mitigations

949 A summary of the email related threats to an enterprise is given in Table 3-1. This includes  
 950 threats to both the email the receiver and the purported sender - often spoofed, and who may not  
 951 be aware an email was sent using their domain. Mitigations are listed in the final column to  
 952 reduce the risk of the attack being successful, or to prevent them.

953 **Table 3-1 Email-based Threats and Mitigations:**

Threat	Impact on Purported Sender	Impact on Receiver	Mitigation
Email sent by unauthorized MTA in enterprise (e.g. malware botnet)	Loss of reputation, valid email from enterprise may be blocked as possible spam/phishing attack.	UBE and/or email containing malicious links may be delivered into user inboxes	Deployment of domain-based authentication techniques (see Section 4). Use of digital signatures over email (see Section 6).
Email message sent using spoofed or unregistered sending domain	Loss of reputation, valid email from enterprise may be blocked as possible spam/phishing attack.	UBE and/or email containing malicious links may be delivered into user inboxes	Deployment of domain-based authentication techniques (see Section 4). Use of digital signatures over email (see Section 6).
Email message sent using forged sending address or email address (i.e. phishing, spear phishing)	Loss of reputation, valid email from enterprise may be blocked as possible spam/phishing attack.	UBE and/or email containing malicious links may be delivered. Users may inadvertently divulge sensitive information or PII.	Deployment of domain-based authentication techniques (see Section 4). Use of digital signatures over email (see Section 6).

Threat	Impact on Purported Sender	Impact on Receiver	Mitigation
Email modified in transit	Leak of sensitive information or PII.	Leak of sensitive information, altered message may contain malicious information	Use of TLS to encrypt email transfer between servers (see Section 5). Use of end-to-end email encryption (see Section 7).
Disclosure of sensitive information (e.g. PII) via monitoring and capturing of email traffic	Leak of sensitive information or PII.	Leak of sensitive information, altered message may contain malicious information	Use of TLS to encrypt email transfer between servers (see Section 5). Use of end-to-end email encryption (see Section 7).
Unsolicited Bulk Email (i.e. spam)	None, unless purported sender is spoofed.	UBE and/or email containing malicious links may be delivered into user inboxes	Techniques to address UBE (see Section 7).
DoS/DDoS attack against an enterprises' email servers	Inability to send email.	Inability to receive email.	Multiple mail servers, use of cloud-based email providers.

954

### 955 3.5 Security Recommendations Summary

956 **Security Recommendation 3-1:** To mitigate the risk of unauthorized sender, an enterprise  
 957 administrator should block outbound port 25 and look to deploy firewall or intrusion detection  
 958 systems (IDS) that can alert the administrator when an unauthorized host is sending mail via  
 959 SMTP to the Internet.

960 **Security Recommendation 3-2:** Virtual Machines that are not involved in the organization's  
 961 email infrastructure should be configured to not run Mail Transfer Agents (MTAs).

962 **Security Recommendation 3-3:** To mitigate the risk of unauthorized receivers, an enterprise  
 963 administrator should block inbound port 25 and look to deploy firewall or intrusion detection  
 964 systems (IDS) that can alert the administrator when an unauthorized host is accepting mail via  
 965 SMTP from the Internet.

## 966 **4 Authenticating a Sending Domain and Individual Mail Messages**

### 967 **4.1 Introduction**

968 RFC 5322 defines the Internet Message Format for delivery over the Simple Mail Transfer  
969 protocol (SMTP) [RFC5321], but in its original state any sender can write any “From” address in  
970 the header. SMTP defines the envelope in which a message is transmitted and identifies an RFC  
971 5321 “From” domain. If the message “From” header differs from this, some SMTP  
972 implementations (such as `sendmail`) will note the discrepancy with the addition of a warning  
973 header. This can however be overridden by the mail administrator, who may have organizational  
974 reasons to ‘spoof’ or rewrite the header, and so both RFC 5321 and RFC 5322 defined “From”  
975 addresses can be aligned to some arbitrary form not intrinsically associated with the originating  
976 IP address. This is the essence of spoofed mail. In addition, any man in the middle can modify a  
977 header or data content. These were the conditions under which mail was sent for many years,  
978 until the rise of malicious spoofing and message modification drove the need to find ways of  
979 authenticating addresses to authorized domains (Section 3.1 offers a fuller review of these  
980 threats).

981 Sender Policy Framework (SPF) [RFC4408] uses the Domain Name System (DNS) to allow  
982 domain owners to create records that associate the domain name with a specific IP address range  
983 of authorized message senders. It is a simple matter for receivers to check the SPF TXT record  
984 in the DNS to confirm that the purported sender of a message is permitted to use that source  
985 address and reject mail that does not come from an authorized IP address. SPF is described in  
986 subsection 4.3 below.

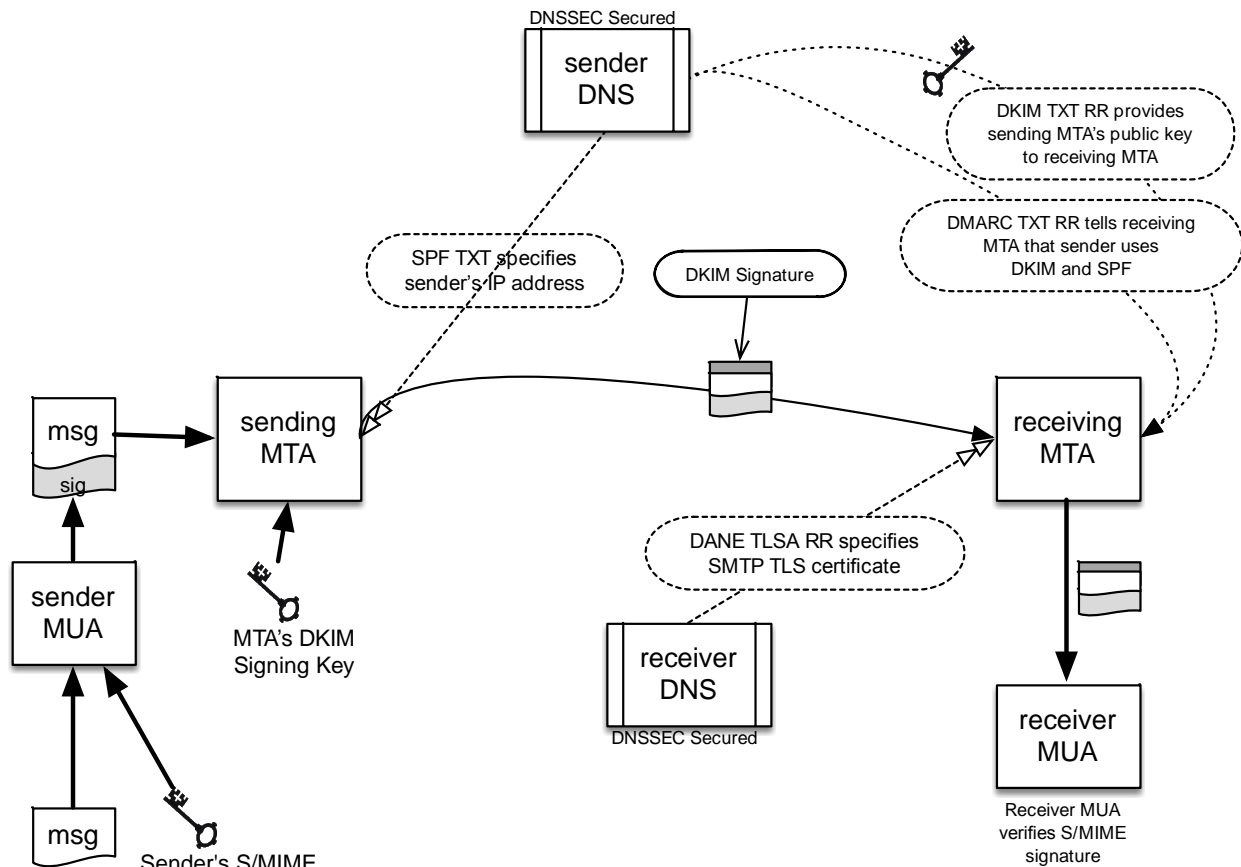

987 A different strategy is adopted for message modification and other man-in-the-middle type  
988 attacks. The Domain Keys Identified Mail (DKIM) [RFC6376] protocol allows software  
989 (typically an MTA) to sign selected headers and the body of the message with a RSA-SHA256  
990 signature and include the signature in a DKIM header that is attached to the message prior to  
991 transmission. The DKIM header includes a selector, which the receiver can use to retrieve the  
992 public key from a record in the DNS, to validate the DKIM signature over the message. In  
993 particular, validating the signature assures the receiver that the message has not been modified in  
994 transit – other than additional headers by MTAs en route which are ignored during the validation.  
995 DKIM is detailed in subsection 4.4.

996 Deploying SPF and DKIM may curb illicit activity against a sending domain, but the sender gets  
997 no indication of the extent of the beneficial (or otherwise) effects of these policies. Senders may  
998 choose to construct pairwise agreements with selected recipients to manually gather feedback,  
999 but this is not a scalable solution. The Domain-based Message Authentication, Reporting and  
1000 Conformance protocol (DMARC) [RFC7489] institutes such a feedback mechanism, to let  
1001 senders know the proportionate effectiveness of their SPF and DKIM policies, and to signal to  
1002 receivers what action should be taken in various individual and bulk attack scenarios. After  
1003 setting a policy to advise receivers to deliver, quarantine or reject messages that fail both SPF  
1004 and DKIM, Email receivers then return DMARC aggregate reports of email dispositions to the  
1005 sender, who can review the results and potentially refine the policy. DMARC is described in  
1006 subsection 4.5.

1007 While DMARC can do a lot to curb spoofing and phishing (Section 3.1.6 above), it does need  
 1008 careful configuration. Mail administrators retain power to rewrite headers for good reasons,  
 1009 usually related to legitimate forwarding activities such as mailing lists, mail groups, and end-user  
 1010 mail forwarding. It should be noted that forwarding changes the source IP address, and without  
 1011 rewriting the “From” field, this makes SPF fail. On the other hand, header rewriting, or adding a  
 1012 footer to mail content, will cause the DKIM signature to fail. Both of these interventions can  
 1013 cause problems for DMARC and for message delivery. Subsection 4.5 expands on the problems  
 1014 of mail forwarding, and its mitigations.

1015 SPF, DKIM and DMARC authenticate that the sending MTA is an authorized, legitimate sender  
 1016 of email messages from that domains. But these technologies do not authenticate that the email  
 1017 message is from a specific individual a role. That kind of assurance is provided by S/MIME. The  
 1018 DKIM and S/MIME signature standards are not-interfering: DKIM signatures go in the RFC 822  
 1019 mail header, while S/MIME signatures are carried as MIME body parts. The signatures are also  
 1020 complementary: a message is typically signed by S/MIME immediately after it is composed,  
 1021 typically by the sender’s MUA, and the DKIM signature is added after the message passes  
 1022 through the sender’s MTA.

1023 The interrelation of SPF, DKIM, DMARC, and S/MIME signatures are shown in the Figure 4-1  
 1024 below:

1025 **Figure 4-1: the interrelationship of DNSSEC, SPF, DKIM, DMARC and S/MIME for assuring message**  
 1026 **authenticity and integrity.**  
 1027

## 1028 4.2 Requirements for Using Domain-based Authentication Techniques for Federal 1029 Systems

1030 As of the time of writing of this guidance document, the DHS Federal Network Resiliency  
1031 (FNR) has called out the use of domain-based authentication techniques for email as part of the  
1032 FY15 FISMA metrics [FISMAMET]. The FY15 metrics include the requirements that federal  
1033 email systems deploy and perform domain-based checks on all outgoing and incoming email.  
1034 This includes the techniques discussed below. This sections gives best-common-practice  
1035 guidance and descriptions of the domain-based authentication techniques described in  
1036 [FISMAMET]. This document does not extend the requirements in anyway, but only attempts to  
1037 give recommendations to meet existing requirements.

## 1038 4.3 Sender Policy Framework (SPF)

1039 Sender Policy Framework (SPF) is a standardized way for a sending domain to identify and  
1040 assert the mail originators (i.e. mail senders) for a given domain. The sending domain does this  
1041 by placing a specially formatted Text Resource Record (TXT RR) in the DNS database for the  
1042 domain. The idea is that a receiving MTA can check the IP address of the original sending MTA  
1043 against the purported sending domain (the portion to the right of the "@" symbol in an email  
1044 address) and see if the domain vouches for the sending MTA. The receiving MTA does this by  
1045 sending a DNS query to the sending domain for the list of valid senders.

1046 SPF was designed to address phishing and spam being sent by unauthorized senders (i.e.  
1047 botnets). SPF does not stop all spam, in that spam email being sent from a domain that asserts its  
1048 sending MTAs via an SPF record will pass all SPF checks. That is, a spammer can send email  
1049 from a domain that the spammer controls, and that email will not be result in an failed SPF  
1050 check. SPF checks fail when mail is received from a sending MTA other than those listed as  
1051 approved senders for a purported domain. For example, an infected botnet of hosts in an  
1052 enterprise may be sending spam on its own (i.e. not through the enterprises outgoing SMTP  
1053 server), but those spam messages would be detected as the infected hosts would not be listed as  
1054 valid senders for the enterprise domain, and would fail SPF checks. See [HERZBERG2009] for a  
1055 detailed review of SPF and its effectiveness.

### 1056 4.3.1 Background

1057 SPF works by comparing the sender's IP address (IPv4 or IPv6, depending on the transport used  
1058 to deliver the message) with the policy encoded in any SPF record found at the sending domain.  
1059 That is, the domain identified in the SMTP envelope (the address used in the SMTP connection),  
1060 not the message header as displayed in the Mail User Agent. This means that SPF checks can  
1061 actually be applied before the bulk of the message is received from the sender. For example, in  
1062 Fig 4-1, the sender with IP address 192.168.0.1 uses the envelope **MAIL FROM:** tag as  
1063 **alice@exmaple.org** even though the message header is **alice.sender@example.net**.  
1064 The receiver queries for the SPF RR for example.com and checks if the IP address is listed as a  
1065 valid sender. If it is, or the SPF record is not found, the message is processed as usual. If not, the  
1066 receiver may mark the message as a potential attack, quarantine it for further (possibly  
1067 administrator) analysis or reject the message, depending on the SPF policy and/or the policy  
1068 discovered in any associated DMARC record (see subsection 4.5, below) for example.com.

```

1069 Client connects to port 25
1070 Server: 220 mx.example.com
1071 Client: HELO mta.example.net
1072 S: 250 Hello mta.example.net, I am glad to meet you
1073 C: MAIL FROM:<alice@example.org>
1074 S: 250 Ok
1075 C: RCPT TO:bob@example.com
1076 S: 354 End data with <CR><LF>.<CR><LF>
1077 C: To: bob@example.com
1078 From: alice.sender@example.net
1079 Date: Today
1080 Subject: Meeting today
1081 ...

```

Fig 4-1: SMTP envelope header vs. message header

1082

1083 Because of the nature of DNS (which SPF uses for publication) an SPF policy is tied to one  
 1084 domain. That is, `@example.com` and `@sub.example.com` are considered separate domains  
 1085 just like `@example.net` and all three need their own SPF records. This complicates things for  
 1086 organizations that have several domains and subdomains that may (or may not) send mail. There  
 1087 is a way to publish a centralized SPF policy for a collection of domains using the `include:` tag  
 1088 (see Sec 4.2.2.2 below)

1089 SPF was first specified in RFC 4408 as an experimental protocol, since at the same time other,  
 1090 similar proposals were also being considered. Over time however, SPF became the preferred  
 1091 solution and was finalized in RFC 7208 (and its updates) [RFC7208]. The changes between the  
 1092 final version and the original version are mostly minor, and those that base their deployments on  
 1093 the experimental version are still understood by clients that implement the final version. The  
 1094 most significant difference is that the final specification no longer calls for the use of a  
 1095 specialized RRTYPE (simply called a SPF RR) and instead calls for the sender policy to be  
 1096 encoded in a TXT Resource Record, in part because it proved too difficult to universally upgrade  
 1097 legacy DNS systems to accept a new RRTYPE. Older clients may still look for the SPF RR, but  
 1098 the majority will fall back and ask for a TXT RR if it fails to find the special SPF RR. RFC 6686,  
 1099 “Resolution of the Sender Policy Framework (SPF) and Sender ID Experiments,” [RFC6686]  
 1100 presents the evidence that was used to justify the abandonment of the SPF RR.

1101 SPF was first called out as a recommended technology for federal agency deployment in 2011  
 1102 [SPF1]. It is seen as a way to reduce the risk of phishing email being delivered and used as to  
 1103 install malware inside an agency's network. Since it is relatively easy to check using the DNS,  
 1104 SPF is seen as a useful layer of email checks.

### 1105 4.3.2 SPF on the Sender Side

1106 Deploying SPF for a sending domain is fairly straightforward. It does not even require SPF  
 1107 aware code in mail servers, as receivers, not senders, perform the SPF processing. The only

1108 necessary actions are identifying all the senders for a given domain, and adding that information  
 1109 in the DNS as a new resource record.

1110 **4.3.2.1 Identifying the Senders for a Domain and Setting the Policy**

1111 The first step in deploying SPF for a sending domain is to identify all the hosts that send email  
 1112 out of the domain (i.e. SMTP servers that are tasked with being email gateways to the Internet).  
 1113 This can be hard to do because:

- 1114 • There may be mail-sending SMTP servers within sub-units of the organization that are  
 1115 not known to higher-level management.
- 1116 • There may be other organizations that send mail on behalf of the organization (such as e-  
 1117 mail marketing firms or legitimate bulk-mailers).
- 1118 • Individuals who work remotely for the organization may send mail using their  
 1119 organization’s email address but a local mail relay.

1120 If the senders cannot be listed with certainty, the SPF policy can indicate that receivers should  
 1121 not necessarily reject messages that fail SPF checks by using the ‘~’ or ‘?’ mechanisms, rather  
 1122 than the ‘-’ mechanism (see 3.2.2 below) in the SPF TXT record.

1123 (Note: Deployment of DMARC [RFC7489] (discussed below) allows for reporting SPF check  
 1124 results back to senders, which allows senders to modify and improve their policy to minimize  
 1125 improper rejections.)

1126 **4.3.2.2 Forming the SPF Resource Record**

1127 Once all the outgoing senders are identified, the appropriate policy can be encoded and put into  
 1128 the domain database. The SPF syntax is fairly rich and can express complex relationships  
 1129 between senders. Not only can entities be identified and called out, but the SPF statement can  
 1130 also request what emphasis should be placed on each test.

1131 SPF statements are encoded in ASCII text (as they are stored in DNS TXT resource records) and  
 1132 checks are processed in left to right order. Every statement begins with **v=spf1** to indicate that  
 1133 this is an SPF (version 1) statement<sup>6</sup>.

1134 Other mechanisms are listed in Table 4-1:

1135

**Table 4-1: SPF Mechanisms**

Tag	Description
<b>ip4:</b>	Specifies an IPv6 address or range of addresses that are authorized senders for a domain.

<sup>6</sup> Note that there is a technology called SenderID that uses "v=spf2.0", but it is not an updated version of SPF, but a different protocol, not recommended in these guidelines.

<b>ip6:</b>	Specifies an IPv6 address or range of addresses that are authorized senders for a domain.
<b>a=:</b>	Asserts that the IP address listed in the domain's primary A RR is authored to send mail.
<b>mx</b>	Asserts that the listed hosts for the MX RR's are also valid senders for the domain.
<b>include:</b>	Lists another domain where the receiver should look for an SPF RR for further senders. This can be useful for large organizations with many domains or sub-domains that have a single set of shared senders. The <b>include:</b> mechanism is recursive, in that the SPF check in the record found is tested in its entirety before proceeding. It is not simply a concatenation of the checks.
<b>all:</b>	Matches every IP address that has not otherwise been matched.

1136

1137 Each mechanism in the string is separated by whitespace. In addition, there are modifiers that  
 1138 can be used for each mechanism (Table 4-2):

1139

**Table 4-2: SPF Mechanism Modifiers**

<b>Modifier</b>	<b>Description</b>
<b>+</b>	The given mechanism check must pass. This is the default mechanism and does not need to be explicitly listed.
<b>-</b>	The given mechanism is not allowed to send email on behalf of the domain.
<b>~</b>	The given mechanism is in transition and if an email is seen from the listed host/IP address, that it should be accepted but marked for closer inspection.
<b>?</b>	The SPF RR explicitly states nothing about the mechanism. In this case, the default behavior is to accept the email. (This makes it equivalent to '+' unless some sort of discrete or aggregate message review is conducted).

1140 There are other mechanisms available as well that are not listed here. Administrators interested  
 1141 in seeing the full depth of the SPF syntax are encouraged to read the full specification in RFC  
 1142 4408. To aid administrators, there are some online tools<sup>7</sup> that can be used assist in the generation  
 1143 and testing of an SPF record. These tools take administrator input and generate the text that the  
 1144 administrator then places in a TXT RR in the given domain's zone file.

---

<sup>7</sup> For example: <http://www.mailradar.com/spf/>

### 1145 4.3.2.3 Example SPF RRs

1146 Some examples of the mechanisms for SPF are given below. In each example, the purported  
1147 sender in the SMTP envelope is **example.com**

1148 The given domain has one mail server that both sends and receives mail. No other system is  
1149 authorized to send mail. The resulting SPF RR would be:

```
1150     example.com  IN TXT  "v=spf1 mx -all"
```

1151 The given enterprise has a DMZ that allows hosts to send mail, but is not sure if other senders  
1152 exist. As a temporary measure, they list the SPF as:

```
1153     example.com  IN TXT  "v=spf1 ip4:192.168.0.1/16 ~all"
```

1154 The enterprise has several domains for projects, but only one set of sending MTAs. So for each  
1155 domain, there is an SPF RR with the **include:** declaration pointing to a central TXT RR with  
1156 the SPF policy that covers all the domains. For example, each domain could have:

```
1157     example.com  IN TXT  "v=spf1 include:spf.example.net."
```

1158 The follow up query for the spf.example.net then has:

```
1159     spf.example.net  IN TXT  "v=spf ip4: 192.168.0.1 ..."
```

1160 This makes SPF easier to manage for an enterprise with several domains and/or public  
1161 subdomains. Administrators only need to edit **spf.example.net** to make changes to the SPF  
1162 RR while the other SPF RR's in the other domains simply use the **include:** tag to reference it.  
1163 No email should originate from the domain:

```
1164     example.com      IN TXT  "v=spf1 -all"
```

1165 The above should be added to all domains that do not send mail to prevent them being used by  
1166 phishers looking for sending domains to spoof that they believe may not be monitored as closely  
1167 as those that accept and send enterprise email. This is an important principle for domains that  
1168 think they are immune from email related threats. Domain names that are only used to host web  
1169 or services are advised to publish a **"-all"** record, to protect their reputation.

1170 Notice that semicolons are not permitted in the SPF TXT record.

1171 **Security Recommendation 4-1:** Organizations should deploy SPF to specify which IP  
1172 addresses are authorized to transmit email on behalf of the domain. Domains controlled by an  
1173 organization that are not used to send email should include an SPF RR with the policy indicating  
1174 that there are no valid email senders for the given domain.

### 1175 4.3.3 SPF and DNS

1176 Since SPF policies are now only encoded in DNS TXT resource records, no specialized software

1177 is needed to host SPF RRs. Organizations can opt to include the old (no longer mandated)  
 1178 unique SPF RRType as well, but it is usually not needed, as clients that still query for the type  
 1179 automatically query for a TXT RR if the SPF RR is not found.

1180 Organizations that deploy SPF should also deploy DNS security (DNSSEC) [RFC4033],  
 1181 [RFC4034], [RFC4035]. DNSSEC provides source authentication and integrity protection for  
 1182 DNS data. Its use is more fully described in Section 5.

#### 1183 4.3.3.1 Changing an Existing SPF Policy

1184 Changing the policy statement in an SPF RR is straightforward, but requires timing  
 1185 considerations due to the caching nature of DNS. It may take some time for the new SPF RR to  
 1186 propagate to all authoritative servers. Likewise, the old, outgoing SPF RR may be cached in  
 1187 client DNS servers for the length of the SPF's TXT RR Time-to-Live (TTL). An enterprise  
 1188 should be aware that some clients might still have the old version of the SPF policy for some  
 1189 time before learning the new version. To minimize the effect of DNS caching, it is useful to  
 1190 decrease the DNS timeout to a small period of time (e.g. 300 seconds) before making changes,  
 1191 and then restoring DNS to a longer time period (e.g. 3600 seconds) after the changes have been  
 1192 made, tested, and confirmed to be correct.

#### 1193 4.3.4 Considerations for SPF when Using Cloud Services or Contracted Services

1194 When an organization outsources its email service (whole or part) to a third party such as a cloud  
 1195 provider or contracted email service, that organization needs to make sure any email sent by  
 1196 those third parties will pass SPF checks. To do this, the enterprises administrator should include  
 1197 the IP addresses of third party senders in the enterprise SPF policy statement RR. Failure to  
 1198 include all the possible senders could result in valid email being rejected due to a failure when  
 1199 doing the SPF check.

1200 Including the third-party's is done by adding the IP addresses/hostnames individually, or using  
 1201 the **include:** tag to reference the third party's own SPF record (if it exists). In general it is  
 1202 preferable to use the **include:** mechanism, as the mechanism avoids hard-coding IP addresses  
 1203 in multiple locations.

1204 For example, if **example.com** has its own sending MTA at 192.0.0.1 but also uses a third party  
 1205 (**third-example.net**) to send non-transactional email as well, the SPF RR for  
 1206 **example.com** would look like:

```
1207 example.com      IN TXT      "v=spf1 ip4:192.0.0.1  
1208                  include:third-example.net -all"  
1209
```

1210 As mentioned above, the **include:** mechanism does not simply concatenate the policy tests of  
 1211 the included domain (here: **third-example.net**), but performs all the checks in the SPF  
 1212 policy referenced and returns the final result. An administrator should not include the modifier  
 1213 "+" (requiring the mechanism to pass in order for the whole check to pass) to the **include:**  
 1214 unless they are also in control of the included domain, as any change to the SPF policy in the

1215 included domain will affect the SPF validation check for the sending domain.

#### 1216 **4.3.5 SPF on the Receiver Side**

1217 Unlike senders, receivers need to have SPF-aware mail servers to check SPF policies. SPF has  
 1218 been around in some form (either experimental or finalized) and available in just about all major  
 1219 mail server implementations. There are also patches and libraries available for other  
 1220 implementations to make them SPF-aware and perform SPF queries and processing<sup>8</sup>. There is  
 1221 even a plug-in available for the open-source Thunderbird Mail User Agent so end users can  
 1222 perform SPF checks even if their incoming mail server does not.<sup>9</sup>

1223 As mentioned above, SPF uses the SMTP envelope **MAIL FROM:** address domain and the IP  
 1224 address of the sender. This means that SPF checks can be started before the actual text of the  
 1225 email message is received. Alternatively, messages can be quickly received and held in  
 1226 quarantine until all the checks are finished. In either event, checks must be completed before the  
 1227 mail message is sent to an end user's inbox (unless the only SPF checks are performed by the end  
 1228 user using their own MUA).

1229 The resulting action based on the SPF checks depends on local receiver policy and the statements  
 1230 in the sender's SPF statement. The action should be based on the modifiers (listed above) on each  
 1231 mechanism. If no SPF TXT RR is returned in the query, or the SPF has formatting errors that  
 1232 prevents parsing, the default behavior is to accept the message. This is the same behavior for  
 1233 mail servers that are not SPF-aware.

##### 1234 **4.3.5.1 SPF Queries and DNS**

1235 Just as an organization that deploys SPF should also deploy DNSSEC [SP800-81], receivers that  
 1236 perform SPF processing should also perform DNSSEC validation (if possible) on responses to  
 1237 SPF queries. A mail server should be able to send queries to a validating DNS recursive server if  
 1238 it cannot perform its own DNSSEC validation.

1239 **Security Recommendation 4-2:** Organizations should deploy DNSSEC for all DNS name  
 1240 servers and validate DNSSEC queries on all systems that receive email.

#### 1241 **4.4 Domain Keys Identified Mail (DKIM)**

1242 DomainKeys Identified Mail (DKIM) is a protocol that allows a domain to vouch for a message  
 1243 its MTA is sending by having its MTA add a digital signature for the message in the message  
 1244 header. The domain need not be the originator of the message. DKIM does not identify spoofed  
 1245 or phishing email, but instead is used to validate authentic email from a sending domain.

1246 A DKIM signature is generated by the original sending MTA using the email message body and  
 1247 headers and places it in the header of the message along with information for the client to use in

---

<sup>8</sup> A list of some SPF implementations can be found at <http://www.openspf.org/Implementations>

<sup>9</sup> See <https://addons.mozilla.org/en-us/thunderbird/addon/sender-verification-anti-phish/>

1248 validation of the signature (i.e. key selector, algorithm, etc.). When the receiving MTA gets the  
1249 message, it attempts to validate the signature by looking for the public key indicated in the  
1250 DKIM signature. It does this using a DNS query for a text resource record (TXT RR) that  
1251 contains the encoded key.

1252 Like SPF (see Section 4.3), DKIM allows for an enterprise to vouch for an email message sent  
1253 by a domain it does not control (as would be listed in the SMTP envelope). DKIM does this by  
1254 storing the public key used to validate the DKIM signature over the message. The sender only  
1255 needs the private portion of the key to generate signatures. This allows an enterprise to have  
1256 email sent on its behalf by an approved third party. The presence of the public key in the  
1257 enterprises' DNS implies there is a relationship.

1258 Since DKIM requires the use of asymmetric cryptographic key pairs, enterprises must have a key  
1259 management plan in place to generate, store and retire key pairs. Administrative boundaries  
1260 complicate this plan if one organization sends mail on another organization's behalf.

#### 1261 **4.4.1 Background**

1262 DKIM was originally developed as part of a private sector consortium and only later transitioned  
1263 to an IETF standard. The threat model that the DKIM protocol is designed to protect against was  
1264 published as RFC 4686 [RFC4686], and assumes bad actors with an extensive corpus of mail  
1265 messages from the domains being impersonated, knowledge of the businesses being  
1266 impersonated, access to business public keys, and the ability to submit messages to MTAs and  
1267 MSAs at many locations across the Internet. The original DKIM protocol specification was  
1268 developed as RFC 4807 [RFC4807], which is now considered obsolete. The specification  
1269 underwent several revisions and updates and the current version of the DKIM specification is  
1270 published as RFC 6376 [RFC6376].

#### 1271 **4.4.2 DKIM on the Sender Side**

1272 Unlike SPF, DKIM requires specialized functionality on the sender MTA to generate the  
1273 signatures. Therefore the first step in deploying DKIM is to insure that the organization has an  
1274 MTA that can support the generation of DKIM signatures. DKIM support is currently available  
1275 in some implementations or can be added using open source filters<sup>10</sup>. Administrators should  
1276 remember that since DKIM involves digital signatures, sending MTAs should also have  
1277 appropriate cryptographic tools to create and store keys and perform cryptographic operations.

#### 1278 **4.4.3 Generation and Distribution of the DKIM Key Pair**

1279 The next step in deploying DKIM, after insuring that the sending MTA is DKIM-aware, is to  
1280 generate a signing key pair.

1281 Cryptographic keys should be generated in accordance with NIST SP 800-57,

---

<sup>10</sup> Mail filters are sometimes called “milters.” A milter is a process subordinate to a MTA that can be deployed to perform special message header or body processing. More information about milters can be found at [http://www.sendmail.com/sm/partners/milter\\_partners/open\\_source\\_milter\\_partners/](http://www.sendmail.com/sm/partners/milter_partners/open_source_milter_partners/)

1282 “Recommendations for Key Management” [SP800-57pt1] and NIST SP 800-133,  
 1283 “Recommendations for Cryptographic Key Generation.” [SP800-133] Although there exist web-  
 1284 based systems for generating DKIM public/private key pairs in X.509 format and automatically  
 1285 producing the corresponding DNS entries, such systems should not be used for federal  
 1286 information systems because they may compromise the organization’s private key.

1287 Currently the DKIM standard specifies that messages must be signed with one of two digital  
 1288 signature algorithms: RSA/SHA-1 and RSA/SHA-256. Of these, only RSA/SHA-256 is  
 1289 approved for use by government agencies with DKIM, as the hash algorithm SHA-1 is no longer  
 1290 approved for use in conjunction with digital signatures (see Table 4-1).

1291

**Table 4-3: Recommended Cryptographic Key Parameters**

DKIM Specified Algorithm	Approved for Government Use?	Recommended Length	Recommended Lifetime
RSA/SHA-1	NO	n/a	n/a
RSA/SHA-256	YES	2048 bits	1-2 years

1292

1293 Once the key pair is generated, the administrator should determine a selector value to use with  
 1294 the key. A DKIM selector value is a unique identifier for the key that is used to distinguish one  
 1295 DKIM key from any other potential keys used by the same sending domain, allowing different  
 1296 MTAs to be configured with different signing keys. This selector value is needed by receiving  
 1297 MTAs to query the validating key.

1298 The public part of the key pair is used to generate the DKIM TXT Resource Record (RR). This  
 1299 record should be added to the organization’s DNS server and tested to make sure that it is  
 1300 accessible both within and outside the organization.

1301 The private part of the key pair is used by the MTA to sign outgoing mail. Administrators must  
 1302 configure their mail systems to protect the private part of the key pair from exposure to prevent  
 1303 an attacker from learning the key and using it to spoof email with the victim domain's DKIM  
 1304 key. For example, if the private part of the key pair is kept in a file, the file must be configured  
 1305 so that only the user under which the MTA is running can read it.

1306 **Security Recommendation 4-3:** Administrators shall only use keys with approved  
 1307 algorithms and lengths for use with DKIM.

1308 **Security Recommendation 4-4:** Administrators should insure that the private portion of the  
 1309 key pair is adequately protected on the sending MTA and that only the MTA software has read  
 1310 privileges for the key.

1311 **Security Recommendation 4-5:** Each sending MTA should be configured with its own  
 1312 private key and its own selector value, to minimize the damage that may occur if a private key is  
 1313 compromised.

1314 **4.4.4 Example of a DKIM Signature**

1315 Below is an example of a DKIM signature as would be seen in an email header. A signature is  
 1316 made up of a collection of **tag=value** pairs that contain parameters needed to successfully  
 1317 validate the signature as well as the signature itself. An administrator usually cannot configure  
 1318 the tags individually as these are done by the MTA functionality that does DKIM, though some  
 1319 require configuration (such as selector, discussed above). Some common tags are:

1320

**Table 4-4: DKIM Signature Tag and Value Descriptions**

Tag	Name	Description
<b>v=</b>	Version	Version of DKIM in use by the signer. Currently the only defined value is "1".
<b>a=</b>	Algorithm	The algorithm used ( <b>rsa-sha1</b> or <b>rsa-sha256</b> )
<b>b=</b>	Signature ("base")	The actual signature, encoded as a base64 string in textual representations
<b>bh=</b>	Signature Hash ("base hash")	The hash of the body of the email message encoded as a base64 string.
<b>d=</b>	DNS	The DNS name of the party vouching for the signature. This is used to identify the DNS domain where the public key resides.
<b>i=</b>	Identifier	Optional agent identifier, which identifies the entity that generated the signature. This may or may not be the same as the domain called out in the <b>d=</b> tag.
<b>s=</b>	Selector	Required selector value. This, together with the domain identified in the <b>d=</b> tag, is used to form the DNS query used to obtain the key that can validate the DKIM signature.
<b>t=</b>	Timestamp.	The time the DKIM signature was generated.
<b>x=</b>	Signature expiration	An optional value to state a time after which the DKIM signature should no longer be considered valid. Often included to provide anti-replay protection.
<b>l=</b>	Length	Length specification for the body in octets. So the signature can be computed over a given length, and this will not affect authentication in the case that a mail forwarder adds an additional

		suffix to the message.
--	--	------------------------

1321

1322 Thus, a DKIM signature from a service provider sending mail on behalf of **example.gov** might  
 1323 appear as an email header:

```
1324     DKIM-Signature: v=1; a=rsa-sha256; d=example.gov; c=simple;
1325     i=@gov-sender.example.com; t=1425066098; s=adkimkey; bh=base64
1326     string; b=base64 string
```

1327 Note that, unlike SPF, DKIM requires the use of semicolons between statements.

1328 **4.4.5 Generation and Provisioning of the DKIM Resource Record**

1329 The public portion of the DKIM key is encoded into a DNS TXT Resource Record (RR) and  
 1330 published in the zone indicated in the FROM: field of the email header. The DNS name for the  
 1331 RR uses the selector the administrator chose for the key pair and a special tag to indicate it is for  
 1332 DKIM ("**\_domainkey**"). For example, if the selector value for the DKIM key used with  
 1333 example.gov is "dkimkey", then the resulting DNS RR has the name  
 1334 **dkimkey.\_domainkey.example.gov**.

1335 Like SPF, there are other **tag=value** pairs that need to be included in a DKIM RR. The full list  
 1336 of tags is listed in the specification [RFC6376], but relevant ones are listed below:

1337 **Table 4-5: DKIM RR Tag and Value Descriptions**

Tag	Name	Description
<b>v=</b>	Version	Version of DKIM in use with the domain and required for every DKIM RR. The default value is " <b>DKIM1</b> ".
<b>k=</b>	Key type	The default is <b>rsa</b> and is optional, as RSA is currently the only specified algorithm used with DKIM
<b>p=</b>	Public Key	The encoded public key (base64 encoded in text zone files). An empty value indicates that the key with the given selector field has been revoked.
<b>t=</b>	Optional flags	One defined flag is " <b>y</b> " indicating that the given domain is experimenting with DKIM and signals to clients to treat signed messages as unsigned (to prevent messages that failed validation from being dropped). The other is " <b>s</b> " to signal that there must be a direct match between the " <b>d=</b> " tag and the " <b>i=</b> " tag in the DKIM signature. That is, the " <b>i=</b> " tag must not be a subdomain of the " <b>d=</b> " tag.

#### 1338 4.4.6 Example of a DKIM RR

1339 Below is an example for the DKIM key that would be used to validate the DKIM signature  
1340 above. Here, not all the flags are given:

```
1341 adkimkey._domainkey.example.gov. IN TXT "v=DKIM1; k=rsa;
1342                                     p=<base64 string>"
1343
```

#### 1344 4.4.7 DKIM and DNS

1345 Since DKIM public keys are encoded in DNS TXT resource records, no specialized software is  
1346 needed to host DKIM public keys. Organizations that deploy DKIM should also deploy DNS  
1347 security (DNSSEC) [RFC4033][RFC4034][RFC4035]. DNSSEC provides source authentication  
1348 and integrity protection for DNS data. This prevents attackers from spoofing, or intercepting and  
1349 deleting responses for receivers' DKIM key TXT queries.

1350 **Security Recommendation 4-6:** Organizations should deploy DNSSEC to provide  
1351 authentication and integrity protection to the DKIM DNS resource records.

#### 1352 4.4.8 DKIM Operational Considerations

1353 There are several operations an email administrator will need to perform to maintain DKIM for  
1354 an email service. New email services are acquired; DKIM keys are introduced, rolled (i.e.  
1355 changed), and eventually retired, etc. Since DKIM requires the use of DNS, administrators need  
1356 to take the nature of DNS into account when performing maintenance operations. A fully  
1357 detailed document of DKIM operations appears in RFC 5863 [RFC5863], but the three most  
1358 common operations are summarized below.

##### 1359 4.4.8.1 Introduction of a New DKIM Key

1360 When initially deploying DKIM for enterprise email, or a new email service to support an  
1361 organization, an administrator should insure that the corresponding public key is available for  
1362 validation. Thus, the DNS entry with the DKIM public portion should be published in the  
1363 sender's domain before the sending MTA begins using the private portion to generate signatures.  
1364 The order should be:

- 1365 1. Generate a DKIM key pair and determine the selector that will be used by the MTA(s).
- 1366 2. Generate and publish the DKIM TXT RR in the sending domain's DNS.
- 1367 3. Ensure that the DKIM TXT RR is returned in queries.
- 1368 4. Configure the sending MTA(s) to use the private portion.
- 1369 5. Begin using the DKIM key pair with email.

##### 1371 4.4.8.2 Changing an Active DKIM Key Pair

1372 DKIM keys may change for various purposes: suspected weakness or compromise, scheduled  
1373 policy, change in operator, or because the DKIM key has reached the end of its lifetime.

1374 Changing, or rolling, a DKIM key pair consists of introducing a new DKIM key before its use  
 1375 and keeping the old, outgoing key in the DNS long enough for clients to obtain it to validate  
 1376 signatures. This requires multiple DNS changes with a wait time between them. The relevant  
 1377 steps are:

- 1378 1. Generate a new DKIM key pair.
- 1379 2. Generate a new DKIM TXT RR, with a different selector value than the outgoing DKIM  
 1380 key and publish it in the enterprise's DNS. *At this point, the DNS will be serving both the*  
 1381 *old and the new DKIM entries*
- 1382 3. Reconfigure the sending MTA(s) to use the new DKIM key.
- 1383 4. Begin using the new DKIM key for signature generation.
- 1384 5. Wait a period of time
- 1385 6. Delete the outgoing DKIM TXT RR.
- 1386 7. Delete or archive the retired DKIM key according to enterprise policy.
- 1387

1388 The necessary period of time to wait before deleting the outgoing DKIM key's TXT RR cannot  
 1389 be a universal constant value due to the nature of DNS and SMTP. An enterprise cannot be  
 1390 certain when all of its email has passed DKIM checks using its old key. An old DKIM key could  
 1391 still be queried for by a receiving MTA hours (or potentially days) after the email had been sent.  
 1392 Therefore the outgoing DKIM key should be kept in the DNS for a period of time (potentially a  
 1393 week) before final deletion.

1394 If it is necessary to revoke or delete a DKIM key, it can be immediately retired by either be  
 1395 removing the key's corresponding DKIM TXT RR or by altering the RR to have a blank `p=`.  
 1396 Either achieves the same effect (the client can no longer validate the signature), but keeping the  
 1397 DKIM RR with a blank `p=` value explicitly signals that the key has been removed.

1398 Revoking a key is similar to deleting it but the enterprise may pre-emptively delete (or change)  
 1399 the DKIM RR before the sender has stopped using it. This scenario is possible when an  
 1400 enterprise wishes to break DKIM authentication and does not control the sender (i.e. a third party  
 1401 or rogue sender). In these scenarios, the enterprise can delete or change the DKIM RR in order  
 1402 to break validation of DKIM signatures. Additional deployment of DMARC (see Section 4.4)  
 1403 can be used to indicate that this DKIM validation failure should result in the email being rejected  
 1404 or deleted.

#### 1405 **4.4.9 DKIM on the Receiver Side**

1406 On the receiver side, email administrators should first make sure their MTA implementation  
 1407 have the functionality to verify DKIM signatures. Most major implementations have the  
 1408 functionality built-in, or can be included using open source patches or a mail filter (milter). In  
 1409 some cases, the administrator may need to install additional cryptographic libraries to perform  
 1410 the actual validation.

##### 1411 **4.4.9.1 DKIM Queries in the DNS**

1412 Just as an organization that deploys DKIM should deploy DNSSEC, receivers that perform

1413 DKIM processing should also perform DNSSEC validation (if possible) on responses to DKIM  
1414 TXT queries. A mail server should be able to send queries to a validating DNS recursive server  
1415 if it cannot perform its own DNSSEC validation.

1416 **Security Recommendation 4-7:** Organizations should enable DNSSEC validation on DNS  
1417 servers used by MTAs that verify DKIM signatures.

#### 1418 **4.4.10 Issues with Mailing Lists**

1419 DKIM assumes that the email came from the MTA that generated the signature. This presents  
1420 some problems when dealing with certain mailing lists. Often, MTAs that process mailing lists  
1421 change the bodies of mailing list messages—for example, adding a footer with mailing list  
1422 information or similar. Such actions will invalidate DKIM signatures.

1423 Fundamentally, mailing lists act as active mail parties. They receive messages from senders and  
1424 resend them to recipients. Sometimes they send messages as they are received, sometimes the  
1425 messages are bundled and sent as a single combined message, and sometimes recipients are able  
1426 to chose their delivery means. As such, mailing lists should verify and then strip the DKIM  
1427 signatures of incoming messages, and then re-sign outgoing messages with their own DKIM  
1428 signature, made with the MTA’s public/private key pair. See RFC 6377, “DomainKeys  
1429 Identified Mail (DKIM) and Mailing Lists” [RFC6377], also identified as IETF BCP 167, for  
1430 additional discussion of DKIM and mailing lists.

1431 Additional assurance can be obtained by providing mailing lists with a role-based S/MIME  
1432 certificate and digitally signing outgoing. Such signatures will allow verification of the mailing  
1433 list signature using S/MIME aware clients such as Microsoft Outlook, Mozilla Thunderbird, and  
1434 Apple Mail. See Sections 2.4.2 and 4.6 for a discussion of S/MIME. Signatures are especially  
1435 important for broadcast mailing lists that are sent with From: addresses that are not monitored,  
1436 such as “do-not-reply” From: addresses.

1437 **Security Recommendation 4-8:** Mailing list software should verify DKIM signatures on  
1438 incoming mail, strip signatures, and re-sign outgoing mail with new DKIM signatures.

1439 **Security Recommendation 4-9:** Mail sent to broadcast mailing lists from do-not-reply or  
1440 unmonitored mailboxes should be digitally signed with S/MIME signatures so that recipients can  
1441 verify the authenticity of the messages.

1442 As with SPF (subsection 4.2 above), DKIM may not prevent a spammer/advertiser from using a  
1443 legitimately obtained domain to send unsolicited, DKIM-signed email. DKIM is used to provide  
1444 assurance that the purported sender is the originator of the message, not the quality or  
1445 appropriateness of the message.

#### 1446 **4.4.11 Considerations for Enterprises When Using Cloud or Contracted Email Services**

1447 An enterprise that uses third party senders for email services needs to have a policy in place for  
1448 DKIM key management. The nature of DKIM requires that the sending MTA have the private  
1449 key in order to generate signatures while the domain owner may only have the public portion.  
1450 This makes key management controls difficult to audit and or impossible to enforce.

1451 Compartmentalizing DKIM keys is one approach to minimize risk when sharing keying material  
1452 between organizations.

1453 When using DKIM with cloud or contracted services, an enterprise should generate a unique key  
1454 pair for each service. No private key should be shared between contracted services or cloud  
1455 instances. This includes the enterprise itself, if email is sent by MTAs operated within the  
1456 enterprise.

1457 **Security Recommendation 4-10:** A unique DKIM key pair should be used for each third  
1458 party that sends email on the organization's behalf.

1459 Likewise, at the end of contract lifecycle, all DKIM keys published by the enterprise must be  
1460 deleted or modified to have a blank `p=` field to indicate that the DKIM key has been revoked.  
1461 This prevents the third party from continuing to send DKIM validated email using the  
1462 enterprise's domain as the purported sender.

#### 1463 **4.5 Domain-based Message Authentication, Reporting and Conformance (DMARC)**

1464 SPF and DKIM were created so that email senders could advise receivers, through the DNS,  
1465 whether mail purporting to originate from them was valid, and thus whether it should be  
1466 delivered, flagged, or discarded. Both SPF and DKIM offer implementation flexibility and  
1467 different settings can have different effects at the receiver. However, neither SPF nor DKIM  
1468 include a mechanism to tell receivers if SPF or DKIM are in use, nor do they have feedback  
1469 mechanism to inform senders of the effectiveness of the anti-spam techniques. For example, if a  
1470 message arrives at a receiver without a DKIM signature, DKIM provides no mechanism to allow  
1471 the receiver to learn if the message is authentic but was sent from a sender that did not  
1472 implement DKIM, or if the message is a spoof.

1473 DMARC allows email senders to specify policy on how their mail should be handled, and the  
1474 frequency and types of report that receivers can send back. DMARC benefits receivers by  
1475 removes the guesswork about which security protocols are in use, allowing more certainty in  
1476 quarantining and rejecting inauthentic mail. In particular, receivers compare the RFC 5322  
1477 defined "From" address in the message to the SPF and DKIM results (if deployed) and the  
1478 DMARC policy in the DNS. The results of this data gathering are used to determine how the  
1479 mail should be handled. DMARC also provides a mechanism that allows receivers to send  
1480 reports to the domain owner about mail claiming to originate from their domain. These reports  
1481 should illuminate the extent to which unauthorized users are using the domain, and the  
1482 proportion of mail received that is from the purported sender.

##### 1483 **4.5.1 DMARC on the Sender Side**

1484 DMARC policies work in conjunction with SPF and/or DKIM, so a mail sender intending to  
1485 deploy DMARC must deploy SPF or DKIM or both. A DMARC sender will publish SPF and/or  
1486 DKIM policies in the DNS, and calculate a signature for the DKIM header of every outgoing  
1487 message. The sender also publishes a DMARC policy in the DNS advising receivers on how to  
1488 treat messages purporting to originate from the sender's domain. The sender does this by  
1489 publishing its DMARC policy as a TXT record in the DNS; identified by creating a `_dmarc`

1490 DNS record the sending domain name. For example, the DMARC policy for “example.gov”  
 1491 would reside at the fully qualified domain name `_dmarc.example.gov`.

1492 Since the sender will be soliciting feedback reports by email from receivers, the sender should  
 1493 establish email addresses to receive aggregate and forensic reports. As the DMARC RR is easily  
 1494 discovered, the reporting inboxes will likely be subject to voluminous unsolicited bulk email (i.e.  
 1495 spam). Therefore, some kind of abuse counter-measures for these email in-boxes should be  
 1496 deployed.

#### 1497 4.5.2 The DMARC DNS Record

1498 The DMARC policy is encoded in a TXT record placed in the DNS by the sender. Similar to  
 1499 SPF and DKIM, the DMARC policy is encoded in a series of `tag=value` pairs separated by  
 1500 semicolons. Common keys are:

1501 **Table 4-6: DMARC RR Tag and Value Descriptions**

Tag	Name	Description
<code>v=</code>	Version	Version field that must be present as the first element. By default the value is always <b>DMARC1</b> .
<code>p=</code>	Policy	Mandatory policy field. May take values ‘ <b>none</b> ’ or ‘ <b>quarantine</b> ’ or ‘ <b>reject</b> ’. This allows for a gradually tightening policy where the sender domain recommends no specific action on mail that fails DMARC checks ( <b>p=none</b> ), through treating failed mail as suspicious ( <b>p=quarantine</b> ), to rejecting all failed mail ( <b>p=reject</b> ), preferably at the SMTP transaction stage.
<code>aspf=</code>	SPF Policy	Values are “ <b>r</b> ” (default) for relaxed and “ <b>s</b> ” for strict SPF domain enforcement. Strict alignment requires an exact match between the RFC 5322 “From” address domain and the (passing) SPF check must exactly match the RFC 5321 “MailFrom” address (i.e. the HELO address). Relaxed requires that only the RFC 5322 “From” and RFC 5321 “MailFrom” address domains be in alignment. For example, the “MailFrom” address domain “ <b>smtp.example.org</b> ” and the RFC 5322 “From” address “ <b>announce@example.org</b> ” are in alignment, but not a strict match.
<code>adkim=</code>	DKIM Policy	Optional. Values are “ <b>r</b> ” (default) for relaxed and “ <b>s</b> ” for strict DKIM domain enforcement. Strict alignment requires an exact match between the RFC 5322 “From” domain in the message header and the DKIM domain presented in the

		<p>“<b>d=</b>” DKIM tag. Relaxed requires only that the domain part is in alignment (as in <b>aspf</b> above).</p>
<b>fo=</b>	Failure Reporting options	<p>Optional. Ignore if a "<b>ruf</b>" argument below is not also present. Value <b>0</b> indicates the receiver should generate a DMARC failure report if all underlying mechanisms fail to produce an aligned “pass” result. Value <b>1</b> means generate a DMARC failure report if any underlying mechanism produces something other than an aligned “pass” result. Other possible values are “<b>d</b>” and “<b>s</b>”: “<b>d</b>” means generate a DKIM failure report if a signature failed evaluation. “<b>s</b>” means generate an SPF failure report if the message failed SPF evaluation. These values are not exclusive and may be combined together in a colon-separated list.</p>
<b>ruf=</b>		<p>Optional, but requires the “<b>fo</b>” argument to be present. Lists a series of Universal Resource Indicators (URI's) (currently just "<b>mailto:</b>&lt;emailaddress&gt;") that list where to send forensic feedback reports. This is for reports on message specific failures. Mail senders should use this argument sparingly, since it is used to request a report on a per-failure basis, which could result in a large volume of failure forensic reports.</p>
<b>rua=</b>		<p>Optional list of URI's (like in <b>ruf=</b> above, using the "<b>mailto:</b>" URI) listing where to send aggregate feedback back to the sender. These reports are sent based on the interval requested using the "<b>ri=</b>" option below, with a default of 86400 seconds if not listed.</p>
<b>ri=</b>	Reporting Interval	<p>Optional with the default value of 86400 seconds (one day). The value listed is the reporting interval desired by the sender.</p>
<b>pct=</b>	Percent	<p>Optional with the default value of <b>100</b>(%). Expresses the percentage of a sender’s mail that should be subject to the given DMARC policy in a range from 0 to 100. This allows senders to ramp up their policy enforcement gradually and prevent having to commit to a rigorous policy before getting feedback on their existing policy. Note: this value must be an integer.</p>
<b>sp=</b>	Receiver Policy	<p>Optional with a default value of ‘<b>none</b>’. Other values include the same range of values as the ‘<b>p=</b>’ argument. This is the policy to be applied to mail from all identified</p>

		subdomains of the given DMARC RR.
--	--	-----------------------------------

1502

1503 Like SPF and DKIM, the DMARC record is actually a DNS TXT RR. Like all DNS  
1504 information, it should be signed using DNSSEC [RFC4033], [RFC4034], and [RFC4035] to  
1505 prevent an attacker from spoofing the DNS response and altering the DMARC check by a client.

### 1506 4.5.3 Example of DMARC RR's

1507 Below are several examples of DMARC policy records using the above tags. The most basic  
1508 example is a DMARC policy that effectively does not assert anything and does not request the  
1509 sender send any feedback reports.

```
1510   _dmarc.example.gov 3600 IN TXT "v=DMARC1; p=none;"
```

1511 An agency that has deployed SPF and DKIM and advises receivers to reject any messages that  
1512 fail these checks would publish a **p=reject** policy as in the example below. Here, the agency  
1513 also wishes to receive aggregate reports from senders on a daily basis (the default).

```
1514   _dmarc.example.gov 3600 IN TXT "v=DMARC1; p=reject;  
1515                                   rua=reports@example.gov;"
```

1516

1517 The agency in the process of deploying DKIM (but has confidence in their SPF policy) may wish  
1518 to receive feedback solely on DKIM failures, but does not wish to be inundated with feedback,  
1519 so requests that the policy be applied to a subset of messages received. In this case, the DMARC  
1520 policy would include the **fo=** option to indicate only DKIM failures are to be reported and a  
1521 **pct=** value of **10** to indicate that only 1 in 10 email messages should be subjected to this policy  
1522 (and subsequent reporting on a failure):

```
1523   _dmarc.example.gov 3600 IN TXT "v=DMARC1; p=none; pct=10; fo=d;  
1524                                   ruf=reports@example.gov;"
```

1525

### 1526 4.5.4 DMARC on the Receiver Side

1527 Receivers of email purporting to originate from a given domain will look up the SPF, DKIM and  
1528 DMARC records in the DNS and act on the policies encoded therein. The typical processing  
1529 order is:

- 1530 1. The receiver extracts the RFC 5322 "From" address from the message. This must  
1531 contain a single, valid address or else the mail is refused as an error.
- 1532 2. The receiver queries for the DMARC DNS record based on the sending domain. If none  
1533 exists, terminate DMARC processing.
- 1534 3. The receiver performs DKIM signature checks. If more than one DKIM signature exists  
1535 in the message, one must verify.

- 1536 4. The receiver queries for the sending domain's SPF record and performs SPF validation  
1537 checks.
- 1538 5. The receiver conducts Identifier Alignment checks between the RFC 5321 "From" and  
1539 the results of the SPF and DKIM records (if present).
- 1540 6. The receiver applies DMARC policy found in the sender's DMARC record unless it  
1541 conflicts with the receiver's local policy. The receiver will also store the results of  
1542 evaluating each received message for the purpose of compiling aggregate reports sent  
1543 back to the sender.

1544 Note that local email processing policy may override a sender's stated DMARC policy. The  
1545 receiver should also store the results of evaluating each received message in some persistent  
1546 form for the purpose of compiling aggregate reports.

#### 1547 4.5.5 Policy and Reporting

1548 DMARC can be seen as consisting of two components: a policy on how email domain based  
1549 authentication protocols should be enforced, and a reporting mechanism. The reason for  
1550 DMARC reporting is so that senders can get feedback on their SPF, DKIM, Identifier Alignment  
1551 and message disposition policies so these can be made more effective. The DMARC protocol  
1552 specifies a system of aggregate reports sent by receivers on a periodic basis, and forensic reports  
1553 sent on a message-by-message basis for email that fail some component part of the DMARC  
1554 checks. The specified form in which receivers send aggregate reports is as a compressed  
1555 (zipped) XML file based on the AFRF format [RFC6591], [RFC7489]. Each aggregate report  
1556 from a mail receiver back to a particular sender includes aggregate figures for successful and  
1557 unsuccessful message authentications including:

- 1558 • The sender's DMARC policy for that interval (Senders may change policies and it is  
1559 undetermined whether a receiver will respond based on the 'old' policy or the 'new'  
1560 policy).
- 1561 • The message disposition by the receiver (i.e. delivered, quarantined, rejected).
- 1562 • SPF result for a given SPF identifier.
- 1563 • DKIM result for a given DKIM identifier.
- 1564 • Whether identifiers are in alignment or not.
- 1565 • Results classified by sender subdomain (whether or not a separate **sp** policy exists).
- 1566 • The sending and receiving domain pair.
- 1567 • The policy applied, and whether this is different from the policy requested.
- 1568 • The number of successful authentications.
- 1569 • Totals for all messages received.

1570 Based on the return flow of aggregate reports from the aggregation of all receivers, a sender can  
1571 build up a picture of the email being sent and how it appears to outside receivers. This allows a  
1572 sender to identify gaps in email infrastructure and policy and how (and when) it can be  
1573 improved. In the early stages of building up this picture, the sending domain should set a  
1574 DMARC policy of **p=none**, so the ultimate disposition of a message that fails some checks rests

1575 wholly on the receiver's local policy. As DMARC aggregate reports are collected, the sender  
 1576 will have a quantitatively better assessment of the extent to which the sender's email is  
 1577 authenticated by outside receivers, and will be able to set a policy of **p=reject**, indicating that  
 1578 any message that fails the SPF, DKIM and alignment checks really should be rejected. From  
 1579 their own traffic analysis, receivers can develop a determination of whether a sender's  
 1580 **p=reject** policy is sufficiently trustworthy to act on.

1581 Forensic reports from receivers to senders help debug and tune the component SPF and DKIM  
 1582 mechanisms as well as altering the sender that their domain is being used as part of a  
 1583 phishing/spam campaign. Typical initial rollout of DMARC in an enterprise will include the  
 1584 **ruf** tag with the values of the **fo** tag progressively modified to capture SPF debugging, DKIM  
 1585 debugging or alignment debugging. Forensic reports are expensive to produce, and bear a real  
 1586 danger of providing a DDoS source back to senders, so when sufficient confidence is gained in  
 1587 the integrity of the component mechanisms, the **ruf** tag may be dropped from DMARC policy  
 1588 statements if the sending domain no longer wants to receive forensic reports.

1589 The same AFRF report format as for aggregate reports [RFC6591], [RFC7489] is also specified  
 1590 for forensic reports, but the DMARC standard updates it for the specificity of a single failure  
 1591 report:

- 1592 • Receivers include as much of the message and message header as is reasonable to allow  
 1593 the domain to investigate the failure.
- 1594 • Add an Identity-Alignment field, with DKIM and SPF DMARC-method fields as  
 1595 appropriate (see above).
- 1596 • Optionally add a Delivery-Result field.
- 1597 • Add DKIM Domain, DKIM Identity and DKIM selector fields, if the message was  
 1598 DKIM signed. Optionally also add DKIM Canonical header and body fields.
- 1599 • Add an additional DMARC authentication failure type, for use when some authentication  
 1600 mechanisms fail to produce aligned identifiers.

#### 1601 **4.5.6 Considerations for Enterprises When Using Cloud or Contracted Email Services**

1602 The **rua** and **ruf** tags typically specify **mailto:** addresses in the sender's domain. These  
 1603 reporting addresses are normally assumed to be in the same domain as the sender, but not  
 1604 always. Cloud providers and contracted services may provide DMARC report collection as part  
 1605 of their service offerings. In these instances, the **mailto:** domain will differ from the sender's  
 1606 domain. To prevent DMARC reporting being used as a DoS vector, the owner of the **mailto:**  
 1607 domain should signal its legitimacy by posting a DMARC TXT DNS record with the Fully  
 1608 Qualified Domain Name (FQDN):

1609 *original-sender-domain.\_report.\_dmarc.mailto-domain*

1610 For example, an original message sent from **example.gov** is authenticated with a DMARC  
 1611 record:

```

1612     _dmarc.example.gov.  IN  TXT  "v=DMARC1; p=reject;
1613                               rua=mailto:reports.example.net"
1614

```

1615 The recipient then queries for a DMARC TXT RR at  
1616 `example.gov._report._dmarc.example.net` and checks the `rua` tag includes the value  
1617 `rua=mailto:reports.example.net` to insure that the address specified in the original  
1618 sender's DMARC record is the legitimate receiver for DMARC reports.

1619 Note that, as with DKIM, DMARC records require the use of semicolons between tags.

#### 1620 4.5.7 Mail Forwarding

1621 The message authentication devices of SPF, DKIM and DMARC are designed to work directly  
1622 between a sender domain and a receiver domain. The message envelope and RFC 5322 defined  
1623 "From" address pass through a series of MTAs, and are authenticated by the receiver. The DKIM  
1624 signature, message headers and message body arrive at the receiver unchanged. The email  
1625 system has additional complexities as there are a variety of message forwarding activity that will  
1626 very often either modify the message, or change the apparent "From" domain. For example  
1627 `user@example.gov` sends a message to `ourgroup@example.net`, which is subsequently forwarded  
1628 to all members of the mail group. If the mail group software simply relays the message, the  
1629 RFC5321 defined "MailFrom" address denoting the forwarder differs from the RFC 5322  
1630 defined "From" address, denoting the original sender. In this case DMARC processing will rely  
1631 on DKIM for authentication. If the forwarder modifies the RFC 5322 defined "From" field to  
1632 match the HELO of the sending MTA (see Section 2.3.1), SPF may authenticate, but the  
1633 modified header will make the DKIM signature invalid. Table 4-2 below summarizes the  
1634 various forwarding techniques and their effect on domain-based authentication mechanisms:

1635 **Table 4-7: Common relay techniques and their impact on domain-based authentication**

Relay Technique	Typical Uses	Negatively Impacts
Aliases	Forwarding, many-to-one consolidation, vanity addresses	SPF
Re-sender	MUA level forwarding, inline forwarding	SPF & DKIM
Mailing Lists	Re-posting to a subscriber list	SPF & DKIM, may lead to rejection and sender unsubscribe
Gateways	Unrestricted message re-writing, and forwarding	SPF & DKIM
Boundary Filters	Spam or malware filters that change/delete content of an email message	SPF & DKIM

1636

1637 Forwarding in general creates problems for DMARC results processing, and as of this writing,  
1638 universal solutions are still in development. There are a currently existing set of mitigations that  
1639 could be used by the mail relay and by the receiver, but would require modified MTA processing  
1640 from traditional SPF and DKIM processing:

- 1641 1. The mediator can alter the RFC 5322 “From” field to match the RFC 5321 SMTP  
1642 envelope address. In this case the SPF lookup would be on the mediator’s domain.
- 1643 2. After making the customary modifications, which break the originators DKIM signature,  
1644 the email relay can generate its own DKIM signature over the modified header and body.  
1645 Multiple DKIM signatures in a message are acceptable and DMARC policy is that at  
1646 least one of the signatures must authenticate to pass DMARC.

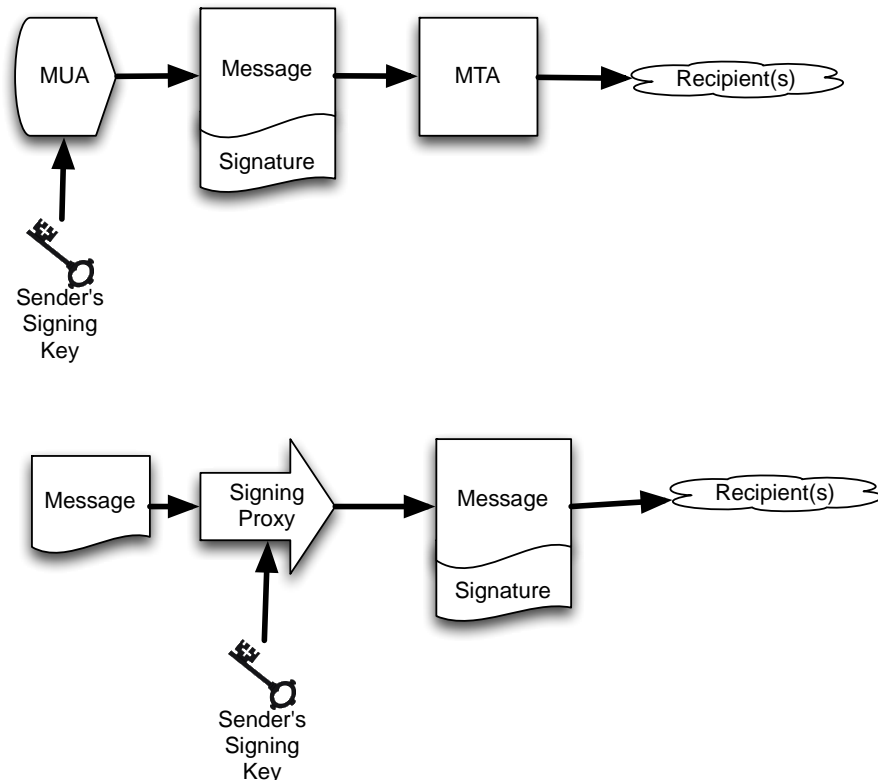

1647 It should also be noted that if one or the other (SPF or DKIM) authentication passes, then  
1648 DMARC policy could be satisfied.

1649 At the receiver side, if a message fails DMARC and is bounced (most likely in the case where  
1650 the sender publishes a **p=reject** policy), then a mailing list may respond by unsubscribing the  
1651 recipient. Mailing list managers should be sensitive to the reasons for rejection and avoid  
1652 unsubscribing recipients if the bounce is due to message authentication issues. If the mailing list  
1653 is in a domain where the recommendations in this document can be applied, then such mailing  
1654 list managers should be sensitive to and accommodate DMARC authentication issues. In the  
1655 case where the mailing list is outside the domain of influence, the onus is on senders and  
1656 receivers to mitigate the effects of forwarding as best they can.

#### 1657 **4.6 Authenticating Mail Messages with Digital Signatures**

1658 In addition to authenticating the sender of a message, the message contents can be authenticating  
1659 with digital signatures. Signed email messages protect against phishing attacks, especially  
1660 targeted phishing attacks, as users who have been conditioned to expect signed messages from  
1661 co-workers and organizations are likely to be suspicious if they receive unsigned messages  
1662 instructing them to perform an unexpected action [GAR2005]. For this reason, the Department of  
1663 Defense requires that all e-mails containing a link or an attachment be digitally signed  
1664 [DOD2009].

1665 Because it interoperates with existing PKI and most deployed software, S/MIME is the  
1666 recommended format for digitally signing messages.

1667 **4.6.1 End-to-End Authentication Using S/MIME Digital Signatures**

1668

1669

**Fig 4-1: Two models for sending digitally signed mail.**

1670 Organizations can use S/MIME digital signatures to certify email that that is sent within or  
 1671 external to the organization. Because support for S/MIME is present in many modern mail  
 1672 clients<sup>11</sup>, S/MIME messages that are signed with a valid digital signature will automatically  
 1673 validate when they are displayed. This is particularly useful for messages that are designed to be  
 1674 read but not replied to—for example, status reports and alerts that are sent programmatically, as  
 1675 well as messages that are sent to announcement-only distribution lists.

1676 To send S/MIME digitally signed messages, organizations must first obtain an S/MIME  
 1677 certificate where the sender matches the “From:” address that will be used to sign the messages.  
 1678 Typically, this will be done with a role-based S/MIME certificate and matching private key,  
 1679 although it can also be done with a certificate that is bound to the name of the individual that is  
 1680 sending the certified message. Once a certificate is obtained, the message is first composed.  
 1681 Next, software uses both the S/MIME certificate and the private portion of their S/MIME key  
 1682 pair to generate the digital signature. S/MIME signatures contain both the signature and the  
 1683 signing certificate, allowing recipients to verify the signed message without having to fetch the  
 1684 certificate from a remote server; the certificate itself is validated using PKI. Sending S/MIME  
 1685 signed messages thus requires either a MUA that supports S/MIME and the necessary

---

<sup>11</sup> Support for S/MIME is included in Microsoft Outlook, Apple Mail, iOS Mail, Mozilla Thunderbird, and other mail programs.

1686 cryptographic libraries to access the private key and generate the signature, or else an  
1687 intermediate program that will sign the message after it is created but before it is delivered (Fig  
1688 4-3).

1689 The receiver of the signed S/MIME message then uses the sender's public key (from the sender's  
1690 attached X.509 certificate) and validates the digital signature. The receiver should also check to  
1691 see if the senders certificate has a valid PKIX chain back to a root certificate the receiver trusts to  
1692 further authenticate the sender. Some organizations may wish to configure MUAs to perform  
1693 real-time checks for certificate revocation and an additional authentication check (See Section  
1694 5.2.2.4).

1695 The principal barrier to using S/MIME for end-user digital signatures has been the difficulty of  
1696 arranging for end-users to obtain S/MIME certificates. One approach is to issue S/MIME  
1697 credentials in physical identity tokens, as is done with the US Government's PIV (Personal  
1698 Identity Verification) cards [FIPS 201]. Individuals can obtain free S/MIME certificates from a  
1699 number of online providers, who verify the individual's address with an email challenge.

1700 The principal barrier to using S/MIME for signing organizational email has been the lack of  
1701 attention to the issue, since only a single certificate is required for signing mail and software for  
1702 verifying S/MIME signatures is already distributed.

1703 **Security Recommendation 4-11:** Use S/MIME signatures for assuring message authenticity  
1704 and integrity.

#### 1705 **4.7 Recommendation Summary**

1706 **Security Recommendation 4-1:** Organizations should deploy SPF to specify which IP  
1707 addresses are authorized to transmit email on behalf of the domain. Domains controlled by an  
1708 organization that are not used to send email should include an SPF RR with the policy indicating  
1709 that there are no valid email senders for the given domain.

1710 **Security Recommendation 4-2:** Organizations should deploy DNSSEC for all DNS name  
1711 servers and validate DNSSEC queries on all systems that receive email

1712 **Security Recommendation 4-3:** Administrators shall only use keys with approved  
1713 algorithms and lengths for use with DKIM.

1714 **Security Recommendation 4-4:** Administrators should insure that the private portion of the  
1715 key pair is adequately protected on the sending MTA and that only the MTA software has read  
1716 privileges for the key.

1717 **Security Recommendation 4-5:** Each sending MTA should be configured with its own  
1718 private key and its own selector value, to minimize the damage that may occur if a private key is  
1719 compromised.

1720 **Security Recommendation 4-6:** Organizations should deploy DNSSEC to provide  
1721 authentication and integrity protection to the DKIM DNS resource records.

- 1722 **Security Recommendation 4-7:** Organizations should enable DNSSEC validation on DNS  
1723 servers used by MTAs that verify DKIM signatures.
- 1724 **Security Recommendation 4-8:** Mailing list software should verify DKIM signatures on  
1725 incoming mail, strip signatures, and re-sign outgoing mail with new DKIM signatures.
- 1726 **Security Recommendation 4-9:** Mail sent to broadcast mailing lists from do-not-reply or  
1727 unmonitored mailboxes should be digitally signed with S/MIME signatures so that recipients can  
1728 verify the authenticity of the messages.
- 1729 **Security Recommendation 4-10:** A unique DKIM key pair should be used for each third  
1730 party that sends email on the organization's behalf.
- 1731 **Security Recommendation 4-11:** Use S/MIME signatures for assuring message authenticity  
1732 and integrity.

## 1733 **5 Protecting Email Confidentiality**

### 1734 **5.1 Introduction**

1735 Cleartext mail messages are submitted by a sender, transmitted hop-by-hop over a series of  
 1736 relays, and delivered to a receiver. Any successful man-in-the-middle can intercept such traffic  
 1737 and read it directly. Any bad actor, or organizationally privileged actor, can read such mail on  
 1738 the submission or delivery systems. Email transmission security can be assured by encrypting the  
 1739 traffic along the path. The Transport Layer Security protocol (TLS) [RFC5246] protects  
 1740 confidentiality by encrypting bidirectional traffic and prevents passive monitoring. TLS relies on  
 1741 public key cryptography and uses X.509 certificates [RFC5280] to store the public key, and the  
 1742 Certificate Authority system to issue certificates and authenticate the origin of the key.

1743 In recent years the CA system has become the subject of attack and has been successfully  
 1744 compromised on several occasions<sup>1213</sup>. The DANE protocol [RFC6698] is designed to overcome  
 1745 problems in the CA system by providing an alternative channel for authenticating public keys  
 1746 based on DNSSEC, with the result that the same trust relationships used to certify IP addresses  
 1747 are used to certify servers operating on those addresses The mechanisms that combine to  
 1748 improve the assurance of email transmission security are described in section 5.2.

1749 Encryption at the transport layer gives assurance of the integrity of data in transit, but senders  
 1750 and receivers who want end-to-end assurance, (i.e. mailbox to mailbox) of confidentiality have  
 1751 two alternative mechanisms for achieving this: S/MIME [RFC5750] and OpenPGP [RFC4880].  
 1752 Both protocol are capable of signing (for authentication) and encryption (for confidentiality).  
 1753 The S/MIME protocol is deployed to sign and/or encrypt message contents, using keys stored as  
 1754 X.509 certificates and a PKI (See Section 2.4.2) while OpenPGP uses a different certificate and a  
 1755 Web-of-Trust model for authentication of identities (See Section 2.4.3). Both of these protocols  
 1756 have the issue of trustworthy certificate publication and discovery. These certificates can be  
 1757 published through the DNS by a different implementation of the DANE mechanism for  
 1758 S/MIME[draft-smime] and OpenPGP [draft-openpgpkey]. S/MIME and OpenPGP, with their  
 1759 strengthening by DANE authentication are discussed below.

### 1760 **5.2 Email Transmission Security**

1761 Email proceeds towards its destination from a Message Submission Agent, through a sequence of  
 1762 Message Transfer Agents, to a Message Delivery Agent, as described in section 2. This  
 1763 translates to the use of SMTP [RFC5321] for submission and hop-by-hop transmission and  
 1764 IMAP [RFC3501] or POP3 [RFC1939] for final delivery into a recipient's mailbox. TLS  
 1765 [RFC5246] can be used to protect email in transit, but intervening hops may be under  
 1766 autonomous control, so a securely encrypted end-to-end path cannot be guaranteed. This is  
 1767 discussed further in section 5.2.1. Opportunistic encryption over some portions of the path can

---

<sup>12</sup> “Comodo SSL Affiliate The Recent RA Compromise,” Phillip Hallam Baker, Comodo, March 15, 2011.  
<https://blog.comodo.com/other/the-recent-ra-compromise/>

<sup>13</sup> Peter Bright, “Independent Iranian hacker claims responsibility for Comodo hack,” Ars Technica, March 28, 2011.  
<http://arstechnica.com/security/2011/03/independent-iranian-hacker-claims-responsibility-for-comodo-hack/>

1768 provide “better-than-nothing” security. The use of STARTTLS [RFC3207] is a standard method  
1769 for establishing a TLS connection. TLS has a secure handshake that relies on asymmetric  
1770 encryption, to establish a secure session (using symmetric encryption). As part of the handshake,  
1771 the server sends the client an X.509 certificate containing its public key, and the cipher suite and  
1772 symmetric key are negotiated with a preference for the optimally strongest cipher that both  
1773 parties support.

1774 From early 2015 there was an initiative in the IETF to develop a standard that allows for the  
1775 implicit (default) use of TLS in email transmission. This goes under the title of Deployable  
1776 Enhanced Email Privacy (DEEP). This scheme goes some steps beyond the triggering of  
1777 STARTTLS, and is discussed further in Section 5.2.4.

1778 Ultimately, the entire path from sender to receiver will be protected by TLS. But this may consist  
1779 of many hops between MTAs, each the subject of a separate transport connection. These are not  
1780 compelled to upgrade to TLS at the same time, however in the patchwork evolutionary  
1781 development of the global mail system, this cannot be completely guaranteed. There may be  
1782 some MTAs along the route uncontrolled by the sender or receiver domains that have not  
1783 upgraded to TLS. In the interim until all mail nodes are certifiably secure, the principle is that  
1784 some incrementally improving security is better than no security, so opportunistic TLS (using  
1785 DANE or other methods to validate certificates) should be employed at every possible hop.

### 1786 **5.2.1 TLS Configuration and Use**

1787 Traditionally, sending email begins by opening a SMTP connection over TCP and entering a  
1788 series of cleartext commands, possibly even including usernames and passwords. This leaves the  
1789 connection exposed to potential monitoring, spoofing, and various man-in-the-middle  
1790 interventions. A clear improvement would be to open a secure connection, encrypted so that the  
1791 message contents cannot be passively monitored, and third parties cannot spoof message headers  
1792 or contents. Transport Layer Security (TLS) offers the solution to these problems.

1793 TCP provides a reliable, flow-controlled connection for transmitting data between two peers.  
1794 Unfortunately, TCP provides no built-in security. Transport connections carry all manner of  
1795 sensitive traffic, including web pages with financial and sign in information, as well as email  
1796 messages. This traffic can only be secured through physical isolation, which is not possible on  
1797 the Internet, or encryption.

1798 Secure Sockets Layer was developed to provide a standard protocol for encrypting TCP  
1799 connections. SSL evolved into Transport Layer Security (TLS), currently at Version 1.2  
1800 [RFC5246]. TLS negotiates a secure connection between initiator and responder (typically client  
1801 and server) parties. The negotiation entails the exchange of the server’s certificate, and possibly  
1802 the client’s certificate, and agreement on a cipher to use for encrypting the data. In essence, the  
1803 protocol uses the public-private key pair: the public key in the server’s certificate, and the  
1804 server’s closely held private key, to negotiate a symmetric key known to both parties, and with  
1805 which both can encrypt, transmit and decrypt the application data. RFC 5246 Appendix A  
1806 describes a range of permissible ciphers, and the parties agree on one from this set. This range of  
1807 ciphers may be restricted on some hosts by local policy (such as only ciphers Approved for  
1808 federal use). Data transmitted over the connection is encrypted using the negotiated session key.

1809 At the end, the connection is closed and the session key can be deleted (but not always, see  
1810 below).

1811 Negotiating a TLS connection involves a significant time and processor load, so when the two  
1812 parties have the need to establish frequent secure connections between them, a session  
1813 resumption mechanism allows them to pick up with the previously negotiated cipher, for a  
1814 subsequent connection.

1815 TLS gains its security from the fact that the server holds the private key securely and the public  
1816 key is authenticated by its being wrapped in an X.509 certificate that is guaranteed by some  
1817 Certificate Authority. If the Certificate Authority is somehow compromised, there is no  
1818 guarantee that the key in the certificate is truly the one belonging to the server, and a client may  
1819 inadvertently negotiate with a man-in-the-middle. An investigation of what X.509 certificates  
1820 are, how they work, and how they can be better secured, follows.

### 1821 **5.2.1.1 Recommendations**

1822 NIST SP 800-52 [SP800-52] provides guidance on the selection and configuration of TLS  
1823 protocol implementations while making effective use of FIPS and NIST recommended  
1824 cryptographic algorithms. NIST SP 800-52 requires that TLS 1.1 configured with FIPS based  
1825 cipher suites as the minimum appropriate secure transport protocol, recommending also that  
1826 agencies develop migration plans to TLS 1.2.

### 1827 **5.2.2 X.509 Certificates**

1828 The Federal Public Key Infrastructure (FPI) Policy Authority has specified profiles (called the  
1829 FPIX profile) for two types of X.509 version 3 certificates that can be used for confidentiality  
1830 and integrity protection of federal email systems [FPI-CERT]. The applicable certificate profile  
1831 is identified by the **KeyPurposeId** with value **id-kp-emailProtection**  
1832 **(1.3.6.1.5.5.7.3.4)** and includes the following:

- 1833 • End Entity Signature Certificate Profile (Worksheet 5)
- 1834 • Key Management Certificate Profile (Worksheet 6)

1835 The overall FPIX profile is an instantiation of IETF's PKI profile developed by the PKIX  
1836 working group (and hence called the PKIX profile) [PKIX] with unique parameter settings for  
1837 Federal PKI systems. Thus a FPIX certificate profile complements the corresponding PKIX  
1838 certificate profile. The following is a brief overview of the two applicable FPIX profiles referred  
1839 above.

#### 1840 **5.2.2.1 X.509 Description**

1841 A trusted Certificate Authority (CA) is licensed to validate applicants' credentials, store their  
1842 public key in a X.509 [x509ref] structure, and digitally sign it with the CA's private key.  
1843 Applicants must first generate their own public and private key pair, save the private key

1844 securely, and bind the public key into an X.509 request. The `openssl req` command is an  
 1845 example way to do this on Unix/Linux systems with OpenSSL<sup>14</sup> installed. Many CAs will  
 1846 generate a certificate without receiving a request (in effect, generating the request themselves on  
 1847 the customer's behalf). The resulting digitally encoded structure is transmitted to the CA, vetted  
 1848 according to the CA's policy, and a certificate is issued. An example certificate is given below  
 1849 in Fig 5-1, with salient fields described.

- 1850 • **Issuer:** The Certificate Authority certificate that issued and signed this end entity  
 1851 certificate. Often this is an intermediate certificate that in turn was signed by either a  
 1852 higher intermediate certificate, or by the ultimate root. If the issuer is a well known  
 1853 reputable entity, its root certificate may be listed in host systems' root certificate  
 1854 repository.
- 1855 • **Subject:** The entity to which this certificate is issued, in this CA. Here:  
 1856 `www.example.com`.
- 1857 • **Public Key:** (this field truncated for convenience). This is the public key corresponding  
 1858 to the private key held by the subject. In use, clients who receive the certificate in a  
 1859 secure communication attempt extract the public key and use it for one of the stated key  
 1860 usages.
- 1861 • **X509v3 Key Usage:** The use of this certificate is restricted to digital signature, key  
 1862 encipherment or key agreement. So an attempt to use it for encryption, for example,  
 1863 should result in rejection.
- 1864 • **X509v3 Basic Constraints:** This document is an end certificate so the constraint is set to  
 1865 `CA:FALSE`. It is not a CA and cannot be used to sign downstream certificates for other  
 1866 entities.
- 1867 • **X509v3 SubjectAltName:** Together with the Common Name in the Subject field, this  
 1868 represents the binding of the public key with a domain. Any attempt by another domain  
 1869 to transmit this certificate to try to establish a connection, should result in failure to  
 1870 authenticate and connection closure.
- 1871 • **Signature Algorithm** (truncated for convenience). The signature generated by the CA  
 1872 over this certificate, demonstrating the CA's authentication of the subject and its public  
 1873 key.

Fig 5-1: Example of X.509 Certificate

### 1934 5.2.2.2 Overview of Key Management Certificate Profile

1935 The public key of a Key Management certificate is used by a device (e.g., Mail Transfer Agent  
1936 (MTA) in our context) to set up a session key (a symmetric key) with its transacting entity (e.g.,  
1937 next hop MTA in our context). The parameter values specified in the profile for this certificate  
1938 type, for some of the important fields are:

- 1939 • **Signature:** (of the cert issuer) If the RSA is used as the signature algorithm for signing the  
1940 certificate by the CA, then the corresponding hash algorithms can only be either SHA-256 or  
1941 SHA-512.
- 1942 • **subjectPublicKeyInfo:** The allowed algorithms for public key are RSA, Diffie-Hellman  
1943 (DH), Elliptic Curve (ECC), or Key Exchange Algorithm (KEA).
- 1944 • **KeyUsage:** The keyEncipherment bit is set to 1 when the subject public key is RSA. The  
1945 KeyAgreement bit is said to 1, when the subject public key is Diffie-Hellman (DH), Elliptic  
1946 Curve (ECC), or Key Exchange Algorithm (KEA).
- 1947 • **KeyPurposeId:** Should include the value `id-kp-emailProtection`  
1948 `(1.3.6.1.5.5.7.3.4)`
- 1949 • **subjectAltName:** Since this certificate is used by devices (as opposed to a human subject),  
1950 this field should contain the DNS name or IP Address.

### 1951 5.2.2.3 X.509 Authentication

1952 The certificate given above is an example of an end certificate. Although it claims to be signed  
1953 by a well-known CA, anyone receiving this certificate in communication has the problem of  
1954 authenticating that signature. For this, full PKIX authentication back to the root certificate is  
1955 required. The CA issues a well-known self-signed certificate containing its public key. This is  
1956 the root certificate. A set of current root certificates, often numbering in the hundreds of  
1957 certificates, are held by individual browser developer and operating system supplier as their set  
1958 of trusted root certificates. The process of authentication is the process of tracing the end  
1959 certificate back to this root certificate, through a chain of zero or more intermediate certificates.

### 1960 5.2.2.4 Certificate Revocation

1961 Every certificate has a period of validity typically ranging from 30 days up to a number of years.  
1962 There may however be reasons to revoke a certificate prior to its expiration, such as the  
1963 compromise or loss of the private key. [RFC5280]. The act of revocation is associated with the  
1964 CA publishing a certificate revocation list. Part of authenticating a certificate chain is perusing  
1965 the certificate revocation list (CRL) to determine if any certificate in the chain is no longer valid.  
1966 The presence of a revoked certificate in the chain results in failure of authentication. Among the  
1967 problems of CRL management, the lack of a truly real-time revocation check leads to non-  
1968 determinism in the authentication mechanism. Problems with revocation led the IETF to develop  
1969 a real-time revocation management protocol, the Online Certificate Status Protocol (OCSP)  
1970 [RFC6960]. Mozilla has now taken the step to deprecate CRLs in favor of OCSP.

### 1971 **5.2.3 STARTTLS**

1972 Unlike the World Wide Web, where the URL indicates that the secure variant (i.e. HTTPS) is in  
 1973 use, an email sender has only the email address, “**user@domain**”, to signal the destination and  
 1974 no way to direct that the channel must be secured. This is an issue not just on a sender to  
 1975 receiver basis, but also on a transitive basis as SMTP is not an end-to-end protocol but instead a  
 1976 protocol that sends mail messages as a series of hops. Not only is there no way to signal that  
 1977 message submission must be secure, there is also no way to signal that any hop in the  
 1978 transmission should be secure. STARTTLS was developed to address some of the shortcomings  
 1979 of this system.

1980 RFC 3207 [RFC3207] describes an extension to SMTP that allows an SMTP client and server to  
 1981 use TLS to provide private, authenticated communication across the Internet. This gives SMTP  
 1982 agents the ability to protect some or all of their communications from eavesdroppers and  
 1983 attackers. If the client does initiate the connection over a TLS-enabled port (e.g. port 465 was  
 1984 previously used for SMTP over SSL) the server may prompt with a message indicating that the  
 1985 STARTTLS option is available. The client can then issue the STARTTLS command in the  
 1986 SMTP command stream, and the two parties proceed to establish a secure TLS connection. An  
 1987 advantage of using STARTTLS is that the server can offer SMTP service on a single port, rather  
 1988 than requiring separate port numbers for secure and cleartext operations. Similar mechanisms are  
 1989 available for running TLS over IMAP and POP protocols.

#### 1990 **5.2.3.1 Recommendations**

1991 **Security Recommendation 5-1:** TLS capable servers must prompt clients to invoke the  
 1992 STARTTLS command. TLS clients should attempt to use STARTTL for SMTP, either initially,  
 1993 or issuing the command when offered.

### 1994 **5.2.4 Deployable Enhanced Email Security (DEEP)**

1995 STARTTLS is an opportunistic protocol. A client may issue the STARTTLS command to initiate  
 1996 a secure TLS connection; the server may support it as a default connection, or may only offer it  
 1997 as an option after the initial connection is established.

1998 The DEEP specification [draft-deep] proposes a security improvement to this protocol by  
 1999 advocating that clients initiate TLS directly over POP, IMAP or SMTP submission software.  
 2000 The specification also proposes a confidence level that indicates an assurance of confidentiality  
 2001 between a given sender domain and a given receiver domain. This aims to provide a level of  
 2002 assurance that current usage does not.

2003 As of the time of writing, DEEP is a work in progress and not ready for deployment. However  
 2004 the principle of client initiation of TLS for email connections should be adhered to in future  
 2005 protocol design. Until DEEP is fully matured and standardized, the use of STARTTLS is  
 2006 recommended for servers to signal to clients that TLS is preferred.

### 2007 **5.2.5 DNS-based Authentication of Named Entities (DANE)**

2008 TLS has for years solved the problem of distributing public keys by using a certificate, signed by

2009 some well-known Certification Authority. Every browser developer and operating system  
 2010 supplier maintains a list of CA root certificates as trust anchors. These are called the software’s  
 2011 “root certificates” and are stored in the “root certificate store.” The PKIX procedure allows the  
 2012 certificate recipient to trace a certificate back to the root. So long as the root certificate remains  
 2013 trustworthy, and the authentication concludes successfully, the client can proceed with the  
 2014 connection.

2015 Currently, there are hundreds of organizations acting as CAs on the Internet, If a CA  
 2016 infrastructure or vetting procedure is compromised, the attacker can obtain the CA’s private key,  
 2017 get issued certificates under a false name, or introduce new bogus root certificates into a root  
 2018 certificate store.. There is no limitation of scope for the global PKI and a compromise of a single  
 2019 CA damages the integrity of the entire PKI system.

2020 Aside from CA compromise, some CAs have engaged in poor security practices. In particular,  
 2021 some CAs have issued wildcard certificates that allow the holder to issue sub-certificates for any  
 2022 domain or entity, anywhere in the world.<sup>15</sup>

2023 DANE introduces mechanisms for domains to specify to clients which certificates should be  
 2024 trusted for the domain. With DANE a domain can declare that clients should only trust  
 2025 certificates from a particular CA or that they should only trust a specific certificate or public key.  
 2026 Essentially, DANE replaces reliance on the security of the CA system with reliance on the  
 2027 security provided by DNSSEC.

2028 The TLS handshake yields an encrypted connection and an X.509 certificate from server to  
 2029 client.<sup>16</sup> The TLS protocol does not define how the certificate should be authenticated. Some  
 2030 implementations may do this as part of the TLS handshake, and some may leave it to the  
 2031 application to decide. Whichever way the implementation goes, there is still a vulnerability: a  
 2032 CA can issue certificates for any domain, and if that CA is compromised (as has happened more  
 2033 than once all too recently), it can issue a replacement certificate for any domain, and take control  
 2034 of that server’s connections. Ideally, certificate issue and delivery should be tied absolutely to  
 2035 the given domain. DANE creates this explicit link by allowing the server domain owner to create  
 2036 a TLSA resource record in the DNS [RFC6698], which identifies the certificate, its public key,  
 2037 or a hash of either. When the client receives an X.509 certificate in the TLS negotiation, it looks  
 2038 up the TLSA RR for that domain and matches the TLSA data against the certificate as part of the  
 2039 clients certificate validation procedure.

2040 DANE has a variety of usage models (called Certificate Usage) to accommodate users who  
 2041 require different forms of authentication. These Certificate Usages are given mnemonic names.

---

<sup>15</sup> For examples of poor CA issuing practices involving sub-certificates, see “Bug 724929—Remove Trustwave Certificate(s) from trusted root certificates,” February 7, 2012. [https://bugzilla.mozilla.org/show\\_bug.cgi?id=724929](https://bugzilla.mozilla.org/show_bug.cgi?id=724929). Also “Bug 698753—Entrust SubCA: 512-bit key issuance and other CPS violations; malware in wild,” November 8, 2011. [https://bugzilla.mozilla.org/show\\_bug.cgi?id=698753](https://bugzilla.mozilla.org/show_bug.cgi?id=698753). Also “Revoking Trust in one CNNIC Intermediate Certificate,” Mozilla Security Blog, March 23, 2015. <https://blog.mozilla.org/security/2015/03/23/revoking-trust-in-one-cnnic-intermediate-certificate/>

<sup>16</sup> Also possibly from client to server.

2042 In usages PKIX-TA and DANE-TA, the TLSA RR contains a trust anchor that issued one of the  
2043 certificates in the PKIX chain, whereas in usages PKIX-EE and DANE-EE, the TLSA RR  
2044 matches an end entity, or leaf certificate. In uses DANE-TA and DANE-EE, the server  
2045 certificate chain is self-issued and does not need (or likely fails) to verify against a trusted root  
2046 stored in the client. In PKIX-TA and PKIX-EE, the server certificate chain must pass PKIX  
2047 validation that terminates with a trusted root certificate stored in the client. As with PKIX  
2048 validation, neither the TLS protocol nor the DANE specification stipulate when DANE  
2049 validation should be done. Some implementations may do it after the connection is negotiated,  
2050 or leave it to the application. A more secure model would be to use a TLS implementation that  
2051 takes care of both PKIX and DANE validations, before presenting a secure open connection to  
2052 the application.

2053 TLS does not offer a client the possibility to specify a particular hostname when connecting to a  
2054 server. This may be a problem in the case where the server offers multiple virtual hosts from one  
2055 IP address, and would prefer to associate a single certificate with a single hostname. RFC 6066  
2056 [RFC6066] defines a set of extensions to TLS that include the Server Name Indication (SNI),  
2057 allowing a client to specifically reference the desired server by hostname and the server can  
2058 respond with the correct certificate. DANE matching condition also requires that the connecting  
2059 server match the SubjectAltName from the delivered end certificate to the certificate indicated in  
2060 the TLSA RR. DANE-EE authentication allows for the server to deliver a self-signed certificate.  
2061 In effect, DANE-EE is simply a vehicle for delivering the public key. Authentication is inherent  
2062 in the trust provided by DNSSEC, and the SNI check is not required.

2063 **Security Recommendation 5-2:** Official use requires certificate chain authentication against  
2064 a known CA and use PKIX-TA or DANE-TA Certificate Usage values when deploying DANE.

### 2065 **5.3 Email Content Security**

2066 End users and their institutions have an interest in rendering the contents of their messages  
2067 completely secure against unauthorized eyes. They can take direct control over message content  
2068 security using either S/MIME [RFC5751] or OpenPGP [RFC4880]. In each of these protocols,  
2069 the sender signs a message with a private key, and the receiver authenticates the signature with  
2070 the public key obtained (somehow) from the sender. Signing provides a guarantee of the message  
2071 source, but any man in the middle can use the public key to decode and read the signed message.  
2072 For proof against unwanted readers, the sender encrypts a message with the recipient's public  
2073 key, obtained (somehow) from the receiver. The receiver decrypts the message with the  
2074 corresponding private key, and the content is kept confidential from mailbox to mailbox. Both  
2075 S/MIME and OpenPGP are protocols that facilitate signing and encryption, but secure open  
2076 distribution of public keys is still a hurdle. Two recent DANE protocols have been proposed to  
2077 address this. The SMIMEA (for S/MIME certificates) and OPENPGPKEY (for OpenPGP keys)  
2078 initiatives specify new DNS RR types for storing email end user key material in the DNS..  
2079 S/MIME and SMIMEA are described in subsection 5.3.1 while OpenPGP and OPENPGPKEY  
2080 are described in subsection 5.3.2.

#### 2081 **5.3.1 S/MIME**

2082 S/MIME is a protocol that allows email users to authenticate messages by digitally signing with

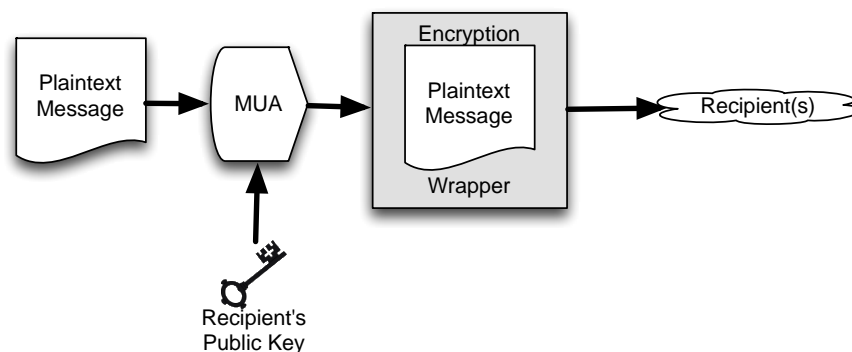

2083 a private key, and including the public key in an attached certificate. The recipient of the  
 2084 message performs a PKIX validation on the certificate, authenticating the message's originator.  
 2085 On the encryption side, the S/MIME sender encrypts the message text using the public key of the  
 2086 recipient, which was previously distributed using some other, out of band, method. Within an  
 2087 organization it is common to obtain a correspondent's S/MIME certificate is from an LDAP  
 2088 directory server. Another way to obtain an S/MIME certificate is by exchanging digitally signed  
 2089 messages.

2090 S/MIME had the advantage of being based on X.509 certificates, allowing existing software and  
 2091 procedures developed for X.509 PKI to be used for email. Hence, where the domain-owning  
 2092 enterprise has an interest in securing the message content, S/MIME is preferred.

2093 The Secure/Multipurpose Internet Mail Extensions (S/MIME) [RFC5751] describes a protocol  
 2094 that will sign, encrypt or compress some, or all, of the body contents of a message. Signing is  
 2095 done using the sender's private key, while encryption is done with the recipient's known public  
 2096 key. Encryption, signing and compression can be done in any order and any combination. The  
 2097 operation is applied to the body, not the RFC822 headings of the message. In the signing case,  
 2098 the certificate containing the sender's public key is also attached to the message.

2099 The receiver uses the associated public key to authenticate the message, demonstrating proof of  
 2100 origin and non-repudiation. The usual case is for the receiver to authenticate the supplied  
 2101 certificate using PKIX back to the certificate Authority. Users who want more assurance that the  
 2102 key supplied is bound to the sender's domain will advocate for the use of the DANE/SMIMEA  
 2103 mechanism [draft-smimea], in which the certificate and key can be independently retrieved from  
 2104 the DNS and authenticated per the DANE mechanism described in subsection 5.2.5, above. The  
 2105 user who wants to encrypt a message retrieves the receiver's public key: which may have been  
 2106 sent on a prior signed message. If no prior signed message is at hand, or if the user seeks more  
 2107 authentication than PKIX, then the key can be retrieved from the DNS in an SMIMEA record.  
 2108 The receiver decrypts the message using the corresponding private key, and reads or stores the  
 2109 message as appropriate.

2110

2111

2112

**Fig 2-4: Sending an Encrypted Email**

2113 To send a S/MIME encrypted message (Fig 2-4) to a user, the sender must first obtain the  
 2114 recipient's X.509 certificate and use the certificate's public key to encrypt the composed

2115 message. When the encrypted message is received, the recipient's MUA uses the private portion  
2116 of the key pair to decrypt the message for reading. In this case the sender must possess the  
2117 recipient's certificate before sending the message.

2118 An enterprise looking to use S/MIME to provide email confidentiality will need to obtain or  
2119 produce credentials for each end user in the organization. An organization can generate its own  
2120 root certificate and give its members a certificate generated from that root, or purchase  
2121 certificates for each member from a well-known Certificate Authority (CA).

2122 Using S/MIME for end-user encryption is further complicated by the need to distribute each end-  
2123 users' certificate to potential senders. Traditionally this is done by having correspondents  
2124 exchange email messages that are digitally signed but not encrypted, since signed messages  
2125 include public keys. Alternatively, organizations can configure LDAP servers to make S/MIME  
2126 public keys available as part of a directory lookup; mail clients such as Outlook and Apple Mail  
2127 can be configured to query LDAP servers for public keys necessary for message encryption.  
2128 Section 5.3 discusses other solutions to that problem based on DNS.

#### 2129 **5.3.1.1 S/MIME Recommendations**

2130 Official use requires certificate chain authentication against a known Certificate Authority.

2131 Current MUAs use S/MIME private keys to decrypt the email message each time it is displayed,  
2132 but leave the message encrypted in the email store. This mode of operation is not recommended,  
2133 as it forces the recipient of the encrypted email to maintain their private key indefinitely. Instead,  
2134 the email should be decrypted prior to being stored in the mail store. The mail store, in turn,  
2135 should be secured using an appropriate cryptographic technique (for example, disk encryption),  
2136 extending protection to both encrypted and unencrypted email. If it is necessary to store mail  
2137 encrypted on the mail server (for example, if the mail server is outside the control of the end-  
2138 user's organization), then the messages should be re-encrypted with a changeable session key on  
2139 a message-by-message basis.

#### 2140 **5.3.2 OPENPGP**

2141 OpenPGP [RFC4880] is a proposed Internet Standard for providing authentication and  
2142 confidentiality for email messages. Although similar in purpose to S/MIME, OpenPGP is  
2143 distinguished by using message and key formats that are built on the "Web of Trust" model (see  
2144 Section 2.4.3, "Pretty Good Privacy (PGP/OpenPGP)").

2145 The OpenPGP standard is implemented by PGP-branded software from Symantec<sup>17</sup> and by the  
2146 open source GNU Privacy Guard.<sup>18</sup> These OpenPGP programs have been widely used by  
2147 activists and security professionals for many years, but have never gained a widespread  
2148 following among the general population owing to usability programs associated with installing  
2149 the software, generating keys, obtaining the keys of correspondents, encrypting messages, and

---

<sup>17</sup> <http://www.symantec.com/products-solutions/families/?fid=encryption>

<sup>18</sup> <https://www.gnupg.org/>

2150 decrypting messages. Academic studies have found that even “easy-to-use” versions of the  
 2151 software that received good reviews in the technical media for usability were found to be not  
 2152 usable when tested by ordinary computer users. [WHITTEN1999]

2153 Key distribution was an early usability problem that OpenPGP developers attempted to address.  
 2154 Initial efforts for secure key distribution involved ‘key distribution parties’, where all  
 2155 participants are known to and can authenticate each other. This method does a good job of  
 2156 authenticating users to each other and building up webs of trust, but it does not scale at all well,  
 2157 and it is not greatly useful where communicants are geographically widely separated.

2158 To facilitate the distribution of public keys, a number of publicly available key servers have been  
 2159 set up and they have been in operation for many years. Among the more popular of these is the  
 2160 pool of SKS key servers<sup>19</sup>. Users can freely upload public key on an opportunistic basis. In  
 2161 theory, anyone wishing to send a PGP user encrypted content can retrieve that user’s key from  
 2162 the SKS server, use it to encrypt the message, and send it However there is no authentication of  
 2163 the identity of the key owners: an attacker can upload their own key to the key server, then  
 2164 intercept the email sent to the unsuspecting user.

2165 A renewed interest in personal control over email authentication and encryption has led to further  
 2166 work within the IETF on key sharing, and the DANE mechanism [draft-openpgp] is being  
 2167 adopted to place a domain and user’s public key in an OPENPGPKEY record in the DNS.  
 2168 Unlike DANE/TLS and SMIMEA, OPENPGPKEY does not use X.509 certificates, or require  
 2169 full PKIX authentication as an option. Instead, full trust is placed in the DNS records as certified  
 2170 by DNSSEC: The domain owner publishes a public key together with minimal ‘certificate’  
 2171 information. The key is available for the receiver of a signed message to authenticate, or for the  
 2172 sender of a message to encrypt.

2173 **Security Recommendation 5-3:** Do not use OpenPGP for message confidentiality. Instead,  
 2174 use S/MIME with a certificate that is signed by a known CA.

### 2175 5.3.2.1 Recommendations

2176 Where an institution requires signing and encryption of end-to-end email, S/MIME is preferred  
 2177 over OpenPGP. Where the DNS performs canonicalization of email addresses, a client  
 2178 requesting a hash encoded OPENPGPKEY RR shall perform no transformation on the left part  
 2179 of the address offered, other than UTF-8 and lower-casing.

## 2180 5.4 Security Recommendation Summary

2181 **Security Recommendation 5-1:** TLS capable servers must prompt clients to invoke the  
 2182 STARTTLS command. TLS clients should attempt to use STARTTLS for SMTP, either initially,  
 2183 or issuing the command when offered

2184 **Security Recommendation 5-2:** Official use requires certificate chain authentication against

---

<sup>19</sup> An incomplete list of well known key servers can be found at <https://www.sks-keyservers.net>

- 2185 a known CA and use PKIX-TA or DANE-TA Certificate Usage values when deploying DANE.
- 2186 **Security Recommendation 5-3:** Do not use OpenPGP for message confidentiality. Instead,  
2187 use S/MIME with a certificate that is signed by a known CA.

## 2188 **6 Reducing Unsolicited Bulk Email**

### 2189 **6.1 Introduction**

2190 Unsolicited Bulk Email (UBE) is often compared to art, in that it is often in the eye of the  
 2191 beholder. To some senders, it is a low-cost marketing campaign for a valid product or service.  
 2192 To many receivers and administrators, it is a scourge that fills up message inboxes and a vector  
 2193 for criminal activity or malware. Both of these views can be true, as the term Unsolicited Bulk  
 2194 Email (or spam, as it is often referred to) comprises a wide variety of email received by an  
 2195 enterprise.

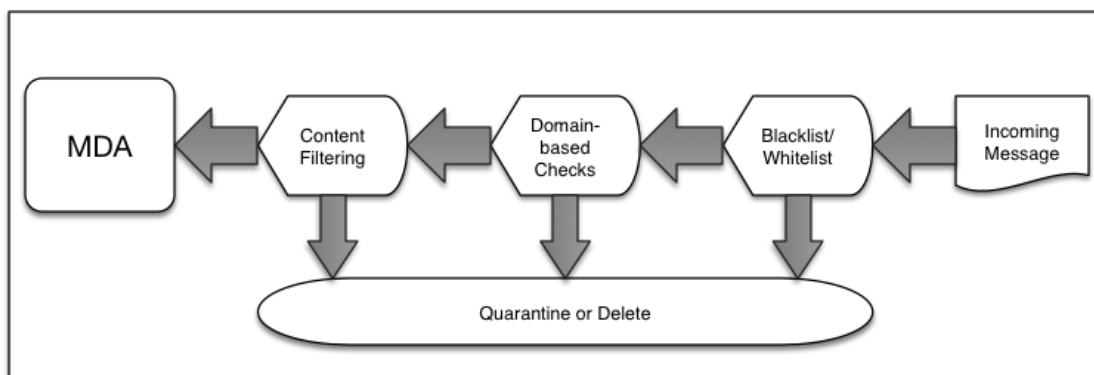

### 2196 **6.2 Why an Organization May Want to Reduce Unsolicited Bulk Email**

2197 While some unsolicited email is from legitimate marketing firms and may only rise to the level  
 2198 of nuisance, it can also lead to increased resource usage in the enterprise. UBE can end up filling  
 2199 up user inbox storage, consume bandwidth in receiving and consume end user's time as they sort  
 2200 through and delete unwanted email. However, some UBE may rise to the level of legitimate  
 2201 threat to the organization in the form of fraud, illegal activity, or the distribution of malware.

2202 Depending on the organization's jurisdiction, UBE may include advertisements for goods or  
 2203 services that are illegal. Enterprises or organizations may wish to limit their employees' (and  
 2204 users') exposure to these offers. Other illegitimate UBE are fraud attempts aimed at the users of  
 2205 a given domain and used to obtain money or private information. Lastly, some UBE is simply a  
 2206 transport aimed at trying to infiltrate the enterprise to install malware.

### 2207 **6.3 Techniques to Reduce Unsolicited Bulk Email**

2208 There are a variety of techniques an email administrator can use to reduce the amount of UBE  
 2209 delivered to end user's inboxes. Enterprises can use one or multiple technologies to provide a  
 2210 layered defense against UBE since no solution is completely effective against all UBE.  
 2211 Administrators should consider using a combination of tools for processing incoming, and  
 2212 outgoing email.

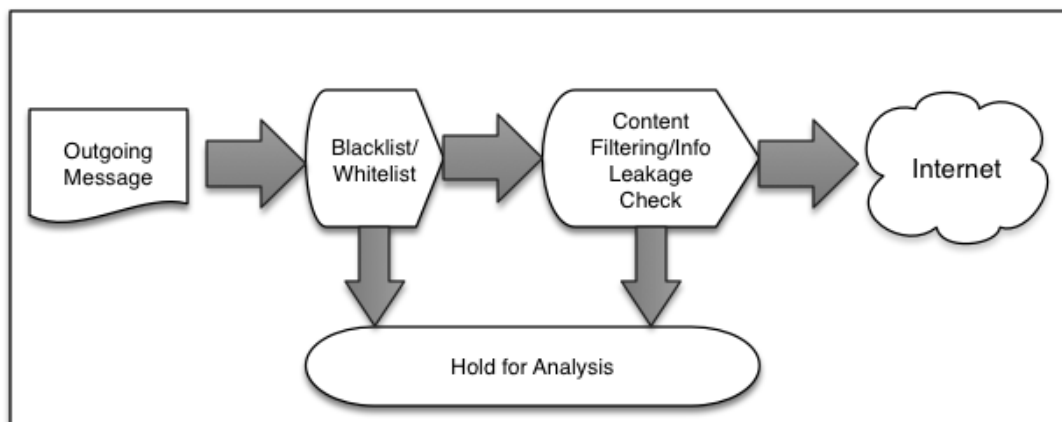

2213

2214

**Fig 6-1 Inbound email "pipeline" for UBE filtering**

2215 These techniques can be performed in serial as a "pipeline" for both incoming and outgoing

2216 email [REFARCH]. Less computationally expensive checks should be done early in the pipeline  
 2217 to prevent wasted effort later. For example, a UBE/SMTP connection that would be caught and  
 2218 refused by a blacklist filter should be done before more computationally expensive content  
 2219 analysis is performed on an email that will ultimately be rejected or deleted. In Figure 6-1, an  
 2220 example pipeline for incoming email checks is given. Fig 6-2 shows an example outbound  
 2221 pipeline for email checks.

2222  
 2223 **Fig 6-2 Outbound email "pipeline" for UBE filtering**

### 2224 6.3.1 Approved/Non-approved Sender Lists

2225 The most basic technique to reduce UBE is to simply accept or deny messages based on some  
 2226 list of known bad or known trusted senders. This is often the first line of UBE defense utilized  
 2227 by an enterprise because if a message was received from a known bad sender, it could reasonably  
 2228 be dropped without spending resources in further processing. Or email originating from a trusted  
 2229 source could be marked so as not to be subject to other anti-UBE checks and inadvertently  
 2230 deleted or thrown out.

2231 A non-approved sender list can be composed of individual IP address, IP block, or sending  
 2232 domain basis [RFC5782]. For example, it is normal for enterprises to refuse email from senders  
 2233 using a source address that has not be allocated, or part of a block reserved for private use (such  
 2234 as 192.168/16). Or an administrator could choose to not accept email from a given domain if the  
 2235 have a reason to assume that they have no interaction with senders using a given domain. This  
 2236 could be the case where an organization does not do business with certain countries and may  
 2237 refuse mail from senders using those ccTLDs.

2238 Given the changing nature of malicious UBE, static lists are not effective. Instead, a variety of  
 2239 third party services produce dynamic lists of known bad UBE senders that enterprise  
 2240 administrators can subscribe to and use. These lists are typically accessed by DNS queries and  
 2241 include the non-commercial ventures such as the Spamhaus Project<sup>20</sup> and the Spam and Open

<sup>20</sup> <https://www.spamhaus.org/>

2242 Relay Blocking System (SORBS)<sup>21</sup>, as well as commercial vendors such as SpamCop.<sup>22</sup> An  
2243 extensive list of DNS-based blacklists can be found at <http://www.dnsbl.info>. Because an  
2244 individual service may be unavailable many organizations configure their mailers to use multiple  
2245 lists. Email administrators should use these services to maintain a dynamic reject list rather than  
2246 attempting to maintain a static list for a single organization.

2247 An approved list is the opposite of a non-approved list. Instead of refusing email from a list of  
2248 known bad actors, an approved list is composed of known trusted senders. It is often a list of  
2249 business partners, community members, or similar trusted senders that have an existing  
2250 relationship with the organization or members of the organization. This does not mean that all  
2251 email sent by members on an approved list should be accepted without further checks. Email sent  
2252 by an approved sender may not be subject to other anti-UBE checks but may still be checked for  
2253 possible malware or malicious links. Email administrators wishing to use approved list should  
2254 be very stringent about which senders make the list. Frequent reviews of the list should also  
2255 occur to remove senders when the relationship ends, or add new members when new  
2256 relationships are formed. Some email tools allow for end users to create their own approved list,  
2257 so administrators should make sure end users does not approve a known bad sender.

2258 A list of approved/non-approved receivers can also be constructed for outgoing email to identify  
2259 possible victims of malicious UBE messages or infected hosts sending UBE as part of a botnet.  
2260 That is, a host or end user sending email to a domain, or setting the "From" address domain to  
2261 one listed in a non-approved receiver list. Again since this is a relatively easy (computational-  
2262 wise) activity, it should be done before any more intensive scanning tools are used.

### 2263 **6.3.2 Domain-based Authentication Techniques**

2264 Techniques that use sending policy encoded in the DNS such as Sender Policy Framework (SPF)  
2265 and DomainKey Identified Mail (DKIM) and Domain-based Message Authentication and  
2266 Reporting Conformance (DMARC) can also be used to reduce some UBE. Receiving MTAs use  
2267 these protocols to see if a message was sent by an authorized sending MTA for the purported  
2268 domain. These protocols are discussed in Section 4 and should be utilized by email  
2269 administrators for both sending and receiving email.

2270 These protocols only authenticate that an email was sent by a mail server that is considered a  
2271 valid email sender by the purported domain and does not authenticated the contents of the email  
2272 message. Messages that pass these checks should not automatically be assumed to not be UBE,  
2273 as a malicious bulk email sender can easily set up and use their own sending infrastructure to  
2274 pass these checks. Likewise, malicious code that uses an end user's legitimate account to send  
2275 email will also pass domain-based authentication checks.

2276 Domain-based authentication checks require more processing by the receiver MTA and thus  
2277 should be performed on any mail that has passed the first set of blacklist checks. These checks  
2278 do not require the MTA to have the full message and can be done before any further and more

---

<sup>21</sup> <http://www.sorbes.net/>

<sup>22</sup> <https://www.spamcop.net/>

2279 computationally expensive content checks.<sup>23</sup>

### 2280 **6.3.3 Content Filtering**

2281 The third type of UBE filtering measures involves analysis of the actual contents of an email  
2282 message. These filtering techniques examine the content of a mail message for words, phrases or  
2283 other elements (images, web links, etc.) that indicate that the message may be UBE.

2284 Examining the textual content of an email message is done using word/phrase filters or Bayesian  
2285 filters [UBE1] to identify possible UBE. Since these techniques are not foolproof, most tools  
2286 that use these techniques allow for administrators or end users to set the threshold for UBE  
2287 identification or allow messages to be marked as possible UBE to prevent false positives and the  
2288 deletion of valid transactional messages.

2289 Messages that contain URLs or other non-text elements (or attachments) can also be filtered and  
2290 tested for possible malware, UBE advertisements, etc. This could be done via blacklisting  
2291 (blocking email containing links to known malicious sites) or by opening the links in a  
2292 sandboxed browser-like component<sup>24</sup> in an automated fashion to record the results. If the  
2293 activity corresponds to anomalous or known malicious activity the message will be tagged as  
2294 malicious UBE and deleted before placed into the end-user's in-box.

2295 Content filtering and URL analysis is more computationally expensive than other UBE filtering  
2296 techniques since the checks are done over the message contents. This means the checks are often  
2297 done after blacklisting and domain-based authentication checks have completed. This avoids  
2298 accepting and processing email from a known bad or malicious sender.

2299 Content filtering could also be applied to outgoing email to identify possible botnet infection or  
2300 malicious code attempting to use systems within the enterprise to send UBE. Some content  
2301 filters may include organization specific filters or keywords to prevent loss of private or  
2302 confidential information.

### 2303 **6.4 User Education**

2304 The final line of defense against malicious UBE is an educated end user. An email user that is  
2305 aware of the risks inherent to email should be less likely to fall victim to fraud attempts, social  
2306 engineering or convinced into clicking links containing malware. While such training may not  
2307 stop all suspicious email, often times an educated end user can detect and avoid malicious UBE  
2308 that passes all automated checks.

2309 How to setup a training regime that includes end user education on the risks of UBE to the  
2310 enterprise is beyond the scope of this document. There are several federal programs to help in  
2311 end user IT security training such as the "Stop. Think. Connect."<sup>25</sup> program from the Department

---

<sup>23</sup> Messages are transmitted incrementally with SMTP, header by header and then body contents and attachments. This allows for incremental and 'just-in-time' header and content filtering.

<sup>24</sup> Sometimes called a "detonation chamber"

<sup>25</sup> <http://www.dhs.gov/stopthinkconnect>

2312 of Homeland Security (DHS). Individual organizations should tailor available IT security  
2313 education programs to the needs of their organization.

2314 User education does not fit into the pipeline model in Section 6.3 above as it takes place at the  
2315 time the end user views the email using their MUA. At this point all of the above techniques  
2316 have failed to identify the threat that now has been placed in the end user's in-box. For outgoing  
2317 UBE, the threat is being sent out (possibly using the user's email account) via malicious code  
2318 installed on the end user's system. User education can help to prevent users from allowing their  
2319 machines to become infected with malicious code, or teach them to identify and remediate the  
2320 issue when it arises.

## 2321 **7 End User Email Security**

### 2322 **7.1 Introduction**

2323 In terms of the canonical email processing architecture as described in Section 2, the client may  
2324 play the role of the MUA. In this section we will discuss clients and their interactions and  
2325 constraints through POP3, IMAP, and SMTP. The range of an end user's interactions with a  
2326 mailbox is usually done using one of two classes of clients: webmail clients and standalone  
2327 clients. These communicate with the mailbox in different ways. Webmail clients use HTTPS.  
2328 These are discussed in section 7.2. Mail client applications for desktop or mobile may use IMAP  
2329 or POP3 for receiving and SMTP for sending and these are examined in section 7.3. There is  
2330 also the case of command line clients, the original email clients, and still used for certain  
2331 embedded system accesses. However these represent no significant proportion of the enterprise  
2332 market and will not be discussed in this document.

### 2333 **7.2 Webmail Clients**

2334 Many enterprises permit email access while away from the workplace or the corporate LAN.  
2335 The mechanisms for this are access via VPN or a web interface through a browser. In the latter  
2336 case the security posture is determined at the web server. Actual communication between client  
2337 and server is conducted over HTTP or HTTPS. Federal agencies implementing a web-based  
2338 solution should refer to NIST SP 800-95 "Guideline to Secure Web Services" [SP800-95] and adhere  
2339 to other federal policies regarding web-based services. Federal agencies are required to provide a  
2340 certificate that can be authenticated through PKIX to a well-known Trust Anchor. An enterprise  
2341 may choose to retain control of its own trusted roots. In this case, DANE can be used to  
2342 configure a TLSA record and authenticate the certificate using the DNS (see Section 5.2.5).

### 2343 **7.3 Standalone Clients**

2344 For the purposes of this guide, "standalone client" refers to a software component used by and  
2345 end user to send and/or receive email. Examples of such clients include Mozilla Thunderbird  
2346 and Microsoft Outlook<sup>26</sup>. These components are typically found on a host computer, laptop or  
2347 mobile device. These components may have many features beyond basic email processing but  
2348 these are beyond the scope of this document.

2349 Sending requires connecting to an MSA or an MTA using SMTP. This is discussed in Section  
2350 7.3.2. Receiving is typically done via POP3 and IMAP,<sup>27</sup> and mailbox management differs in  
2351 each case.

#### 2352 **7.3.1 Sending via SMTP**

2353 Email message submission occurs between a client and a server using the Simple Mail Transfer

---

<sup>26</sup> These clients are given as an example and should not be interpreted as an endorsement.

<sup>27</sup> Other protocols (MAPI/RPC or proprietary protocols) will not be discussed.

2354 Protocol (SMTP) [RFC5321], either using port 25 or 993. The client is operated by an end-user  
2355 and the server is hosted by a public or corporate mail service. It is recommend that the  
2356 connection between the client and MSA is secured using TLS [RFC5246]. The range of  
2357 protective measures described in Section 5.2 Email Transmission Security.

### 2358 **7.3.2 Receiving via IMAP**

2359 Email message receiving and management occurs between a client and a server using the Internet  
2360 Message Access Protocol (IMAP) protocol [RFC3501] over port 143. A client may be located  
2361 anywhere on the Internet, establish a transport connection with the server, authenticate itself, and  
2362 manipulate the remote mailbox with a variety of commands. Depending on the server  
2363 implementation it is feasible to have access to the same mailbox from multiple clients. IMAP  
2364 has operations for creating, deleting and renaming mailboxes, checking for new messages,  
2365 permanently removing messages, parsing, searching and selective fetching of message attributes,  
2366 texts and parts thereof. It is equivalent to local control of a mailbox and its folders.

2367 Establishing a connection with the server over TCP and authenticating to a mailbox with a  
2368 username and password sent without encryption is not recommended. IMAP clients should  
2369 connect to servers using TLS [RFC5246], associated with the full range of applicable protective  
2370 measures described in Section 5.2, Email Transmission Security.

### 2371 **7.3.3 Receiving via POP3**

2372 Before IMAP [RFC3501] was invented, the Post Office Protocol (POP3) had been created as a  
2373 mechanism for remote users of a mailbox to connect to, download mail, and delete it off the  
2374 server. It was expected at the time that access be from a single, dedicated user, with no conflicts.  
2375 Provision for encrypted transport was not made.

2376 The protocol went through an evolutionary cycle of upgrade, and the current instance, POP3  
2377 [RFC5034] is aligned with the Simple Authentication Security Layer (SASL) [RFC4422] and  
2378 optionally operated over a secure encrypted transport layer, TLS [RFC5246]. POP3 defines a  
2379 simpler mailbox access alternative to IMAP, without the same fine control over mailbox file  
2380 structure and manipulation mechanisms. Users who access their mailboxes from multiple hosts  
2381 or devices are recommended to use IMAP clients instead, to maintain synchronization of clients  
2382 with the single, central mailbox.

2383 Clients with POP3 access should configure them to connect over TLS, associated with the full  
2384 range of protective measures described above in Section 5.2 Email Transmission Security.

## 2385 **7.4 Mailbox Security**

2386 The security of data in transit is only useful if the security of data at rest can be assured. This  
2387 means maintaining confidentiality at the sender and receiver endpoints of:

- 2388 • The user's information, and
- 2389 • Private keys for encrypted data.

2390 Confidentiality and encryption for data in transit is discussed in Section 7.4.1, while

2391 confidentiality of data at rest is discussed in Section 7.4.2.

#### 2392 **7.4.1 Confidentiality of Data in Transit**

2393 A common element for users of TLS for SMTP, IMAP and POP3, as well as for S/MIME and  
 2394 OpenPGP, is the need to maintain current and accessible private keys, as used for decryption of  
 2395 received mail, and signing of authenticated mail. A range of different users require access to  
 2396 these disparate private keys:

- 2397 • The email server must have use of the private key used for TLS and the private key must  
 2398 be protected.
- 2399 • The end user (and possibly an enterprise security administrator) must have access to  
 2400 private keys for S/MIME or OpenPGP message signing and decryption.

2401 Special care is needed to ensure that only the relevant parties have access and control over the  
 2402 respective keys. For federal agencies, this means compliance with all relevant policy and best  
 2403 practice on protection of key material [SP800-57pt1].

#### 2404 **7.4.2 Confidentiality of Data at Rest**

2405 This publication is about securing email and its associated data. This is one aspect of securing  
 2406 data in motion. To the extent that email comes to rest in persistent storage in mailboxes and file  
 2407 stores, there is some overlap with NIST SP 800-111 “Guide to Storage Encryption Technologies  
 2408 for End User Devices” [SP800-111].

2409 There is an issue in the tradeoff between accessibility and confidentiality when using mailboxes  
 2410 as persistent storage. End users and their organizations are expected to manage their own private  
 2411 keys, and historical versions of these may remain available to decrypt mail encrypted by  
 2412 communicating partners, and to authenticate (and decrypt) cc: mail sent to partners, but also  
 2413 stored locally. Partners who sign their mail, and decrypt received mail, make their public keys  
 2414 available through certificates, or through DANE records (i.e. TLSA, OPENPGPKEY, SMIMEA)  
 2415 in the DNS. These certificates generally have a listed expiry date and are rolled over and  
 2416 replaces with new certificates containing new keys. Such partners’ mail stored persistently in a  
 2417 mailbox beyond the key expiry and rollover date may cease to be readable if the mailbox owner  
 2418 does not maintain a historical inventory of partners’ keys and certificates. For people who use  
 2419 their mailboxes as persistent, large-scale storage, this can create a management problem. If keys  
 2420 cannot be found, historical encrypted messages cannot be read.

2421 We recommend that email keys for S/MIME and OpenPGP only be used for messages in transit.  
 2422 Messages intended for persistent local storage should be decrypted, stored in user controllable  
 2423 file store, and if necessary re-encrypted with user controlled keys. For maximum security all  
 2424 email should be stored encrypted—for example, with a cryptographic file system.

2425 **Appendix A—Acronyms**

2426 Selected acronyms and abbreviations used in this paper are defined below.

DHS	Department of Homeland Security
DKIM	Domain Keying
DMARC	Domain-based Message Authentication, Reporting and Conformance
DNS	Domain Name System
DNSSEC	Domain Name System Security Extensions
FISMA	Federal Information Security Management Act
FRN	Federal Network Resiliency
IMAP	Internet Message Access Protocol
MDA	Mail Delivery Agent
MSA	Mail Submission Agent
MTA	Mail Transport Agent
MUA	Mail User Agent
MIME	Multipurpose Internet Message Extensions
NIST SP	NIST Special Publication
PGP/OpenPGP	Pretty Good Privacy
PKI	Public Key Infrastructure
POP3	Post Office Protocol, Version 3
RR	Resource Record
S/MIME	Secure/Multipurpose Internet Mail Extensions
SMTP	Simple Mail Transport Protocol
SPF	Sender Policy Framework
TLS	Transport Layer Security
VM	Virtual Machine
VPN	Virtual Private Network
